However, there are conditions that are unfavorable for palynomorph preservation and subsequent analysis. Palynomorphs will oxidize when exposed to weathering, and they cannot survive in high-alkaline conditions. Because the carbonization of chitin and sporopollenin occurs at temperatures over 200°C, palynomorphs are destroyed in strata cooked by lava flows or igneous intrusions, and do not survive the processes of temperature and pressure into

metamorphic or recrystallized rocks. Another challenge is that even in modern times it is difficult to match transported pollen and spores to the species of plant from which it originated, and even harder to match fossilized palynomorphs to a taxon that may not exist anymore.

History

The study of fossil plants dates back to the 6th century B.C. when fossil leaf compressions were noted by the Greek Xenophanes, but the identification and development of microscopic pollen as a scientific tool was to go unrecognized for some time, dependent upon prerequisite advances in magnification technology. Even after pollen was first observed microscopically around 1640, its scientific potential was not realized until the late 19th century when the German geologist Ehrenberg theorized that peat bogs and lake mud would contain pollen records. The commonly accepted date for the establishment of pollen analysis as a study is 1916, when Von Post published material on how to reconstruct ancient vegetation by counting the types of pollen it shed, layer by layer, in the growing peat bogs of Sweden. Then in 1944 Hyde and Williams coined the term *palynology*, from the Greek, meaning "I sprinkle," cognate with the Latin "fine flour" or "dust." Their definition became "the study of pollen and other spores and their dispersal, and applications thereof" but has since been revamped to include other organic microfossils in the range of 5 to 500 microns, not being made of calcium carbonate and resistant to acid digest, thus forming the collective *palynomorphs*.

Examples

The rapid growth and development of palynology in the latter part of the 20th century was in response to its most important economic application, the oil and gas industry. Palynological techniques offer relatively cheap and quick strata dates compared to other methods, providing data during the expensive drilling process and allowing optimization of fieldwork. Palynomorphs' rapid evolutionary changes can help to provide a more accurate chronology of geological sequences and to correlate stratigraphy between exploration wells. In addition, the identification of indicative palynomorphs can lead to the discovery of hydrocarbon deposits in several ways. To produce

useful hydrocarbons, organic-rich sediment needs to undergo a period of “cooking” or maturation. The duration and temperature of this process largely determines the nature of the product, whether it becomes oil, condensate, or gas. By examining and comparing the depth of color in spore exines, an estimate of sediment maturity and prospectivity can be made. It has also been found that palynomorphs can migrate through porous rocks along with the target petroleum products, so their very presence in certain strata can indicate that hydrocarbons are close by.

Palynology has been increasingly used in the field of archaeology and is now applied routinely in many investigations. Pollen and spore analysis can help track the cultivation and domestication of plants as well as the human impact on vegetation, and it can reveal exquisite details of prehistoric life when found associated with artifacts, burial sites and archeological features. In the celebrated discovery of “the ice man,” a 5300-year-old human corpse preserved by an Austrian Alp glacier, the colon contents contained 30 different types of pollen, two spore types, and 24 diatom species. Most of the pollen was ingested as swallowed food and showed a diet predominant in legumes and cereals including einkorn, an ancient wheat grain previously thought to be consumed only by livestock. Pollen grains trapped within the man’s clothing indicated the path and direction from whence he travelled, and even the season in which he met his demise.

Palynology in the service of paleontology is usually used to date strata in which fossils occur, but can also enhance our understanding of the environments and diets of prehistoric animals. The discovery of a naturally mummified brachylophosaurus with intact stomach contents allowed identification of pollen and spores forming not only the cretaceous flora, but also presumably the diet of this 77-million-year-old dinosaur.

Honey contains abundant pollen that palynologists use in the fields of economic science and archaeology. The plants which bees in the Nile valley visited several thousand years ago can be inferred from pollen in honey found in ancient Egyptian tombs. The pollen residues in old drinking horns would technically allow reconstruction of the Viking recipe for mead. Today, apiarists and the food industry use palynology to examine bees’ foraging habits and pollen load variations to assist the development of honey production. It has also been applied as a new

tool in the protection of consumers from fraudulent labeling and food “forgery”: Palynological analysis of provincially unique foodstuffs can detect the presence of foreign pollen, indicating that the food has been mixed with cheaper substitutes or revealing other deceptive trade practices.

Another recent application of palynology is in the field of forensic science, where it has now emerged as a powerful tool to solve crimes. Particularly in outdoor crimes where palynomorphs can drift unseen on air currents, settling on clothes or adhering to certain objects, the analysis of pollen and spores can provide compelling scientific evidence for a jury. It is often possible to be very specific about when and where a person or object has been from the pollen types that occur together in a sample. In one example, a man went missing near Vienna; although the police held a suspect for murder, the body could not be located. Palynological analysis of soil adhering to the suspect’s shoes revealed a mixture of pine and alder pollen, but also traces of older, Oligocene-age pollen. This unique combination pointed to a specific location just south of Vienna where pine and alder trees grow on Oligocene strata. When confronted with this knowledge, the suspect quickly confessed and the missing man’s body was recovered.

Palynology is of great importance in describing changes in tree population with time, thereby allowing inference of past climate changes. The prospect of rapid, trace-gas-induced climate change over the next 100 to 150 years has raised scientific and public interest in the rates at which plant species, particularly tree species, can respond to these changes. Because palynomorphs are sensitive to any minor fluctuation in their surroundings, they are highly indicative of the environment in which they are deposited. Any changes brought about by climatic fluctuations or the activities of man are often recorded in bog or lake sediments as changes in the pollen assemblage. For example, in some Pleistocene-age, interglacial sediments, the palynological analysis reveals the major climatic changes reflected in the tree population. During the cool conditions just before the ice sheet retreated, palynomorphs of a pine and birch assemblage with lots of grasses demonstrated the pretemperate climate; then, as the ice receded during the interglacial period, warmth-loving oak, hazel, and alder trees appeared in the sedimentary record, followed by the anticipated return of pine, birch, and grass as the ice sheet

re-advanced in the succeeding glacial period when temperatures dropped.

Although the primary practice of palynological sample collection and preparation has not evolved much since the relatively recent birth of palynology as a science, there has been explosive growth in applications to many fields. Further advances in palynology can only continue to provide a better picture of our planet's history with which to approach our immediate and long-term future.

Panama is a central American country, with a population of 2,839,170 (2000). It shares borders with Costa Rica to the west and Colombia to the east. Panama's social, economic, political, and cultural history has been marked by its strategic geopolitical location. Panamanian intellectuals have considered their republic a "place of transit," and have struggled to develop an identity to define a country characterized by large temporary and permanent migrations. During colonial times, (early 16th to mid-19th century) Panama (known then as Castilla de Oro) became a tactical site for the Spanish Empire, as it was a point of connection between the Caribbean and the Pacific, and therefore a communications node

between the Viceroyalty of New Granada (with its capital in Mexico City) and the Peruvian Viceroyalty administered from Lima. Slavery (1508–1852) in Panama was not closely linked, as in other regions of America, to plantation life, although some slave labor was used for tobacco and sugar plantations. The economy of colonial Panama rested on six major activities: mining, agriculture, cattle herding, handicraft production, commerce, and domestic work. The most important of these was mining, which used black labor almost entirely. Black labor and, to a lesser degree, indigenous labor were used to build roads and infrastructure to support the Spanish Crown's transportation of wealth. For instance, 60% of the total production of silver in the Viceroyalty of Peru passed through Panama. In addition, Panama served as a major port for transshipment of slave labor to other Spanish colonies.

As a result of this strategic position, Panama's history is marked by a series of important infrastructure projects with consequent transformations for the society. From 1850 to 1855, the Panama Railroad was built as a suitable route to facilitate communication between the West and East of the United States. From 1880 to 1890, the French Company of the Isthmus worked toward the construction of the Panama Canal under the direction of Count Ferdinand de Lesseps (whose major work prior to this was the Suez Canal). By 1884, there were more than 18,000 workers on the project. However, the project was an economic failure that left stranded the thousands of workers brought from the Caribbean, Europe, and China. During the first decade of the 20th century, the United States oversaw the construction of the Panama Canal (1904–1914), and enlisted more than 45,000 workers to continue this monumental task. Most of these workers resided on Barbados and other Caribbean islands. Workers from Colombia, England, France, Germany, India, Austria, and China also worked on the project.

Another element essential to understand Panama is its relationship with Colombia. Panama became a colony of the Spanish Empire in the early 1500s. It became independent from Spain in 1821, and in 1822 it voluntarily allied itself to Colombia, then known as New Grenada, and throughout the 19th century was a neglected province of New Grenada. Some scholars argue that failed negotiations with Colombia for the construction of a transisthmian canal led the United States to support Panama's independence from

Colombia in 1903. Most Panamanian scholars, however, emphasize that a movement toward independence was already in effect, and that the United States did not participate in Panama's process of independence, noting that between the years of 1862 and 1903 there were more than 50 rebellions to establish independence from Colombia. This contentious issue continues to be an important debate in the historical memory of Panamanians.

The Panama Canal was officially finished in 1914. Due to a series of treaties signed by the Panamanian and United States governments, the territory that was christened the Canal Zone became a territory of the United States. From then until the return of the Canal to Panama on December 31, 1999, Panama has struggled to assert its sovereignty over the Canal Zone. As a result of this constant presence, and of Panama's condition of virtual protectorate of the United States, Panamanian intellectuals have emphasized the need to develop a strong national character for the country. This situation has produced a marked yet contradictory nationalism, a blend of xenophilic and xenophobic feelings toward foreign influences and culture.

Panama's condition of "place of transit" has also influenced the country's racial makeup. Panama is a very diverse country, with eight different indigenous groups (Ngöbe, Buglé, Bokotá, Emberá, Wounaan, Bri Bri (recent migrants from Costa Rica), Kuna, and Teribe (or Naso), two distinctive Afro-Panamanian groups (Afro-Colonials and Afro-Antilleans), Mestizo peasant groups, and a Mestizo elite that considers itself white. There are also Asian minorities (Chinese and East Indian in particular), as well as Greek, Italian, and Spanish minorities. Statistical findings establish that 60% of the population identifies as Mestizo, 20% as black and mulatto, 10% as indigenous, 10% as black, and 2% as Asian. As with any other Latin American country, there are distinctive social, political, and economic inequalities in Panama.

Mestizaje became the fundamental founder of this country's cultural identities. Ethnic identity has been shaped by the competition between Britain, the United States, and Central American states. The presence of a variety of ethnic and racial groups has produced the illusion of a country devoid of racism, a true Latin American "melting pot" or, as Panamanians call it, "un crisol de razas." However, racism against black and indigenous populations is a constant reality. When Dr. Arnulfo Arias Madrid, a Harvard-trained Panamanian physician, was elected president in 1940,

he developed the idea of "races of prohibited migration" and changed the Panamanian Constitution in 1941 (also known as the *Panameñista* Constitution) to prevent the arrival of persons of African and Chinese descent unless they were able to speak Spanish and had knowledge of Panamanian history. Although these clearly racist attitudes were modified in an amendment to the Constitution in 1946, as of today, the Panamanian Constitution does not consider Panama a pluriethnic or multicultural nation.

Afro-Antillean and indigenous groups have been particularly affected by racism. Afro-Antilleans have migrated to Panama since the 1820s to work on banana plantations, the Panamanian railroad, and the French and United States efforts to build the Panama Canal. Afro-Antilleans were brought to the Isthmus from different islands of the British West Indies such as Grenada, Saint Lucia, and Antigua but mostly from Jamaica and Barbados. They also came from Haiti, Martinique, and Cuba, and they constituted the largest ethnic group to work in the construction of these infrastructure projects. However, since their migration to the country Afro-Antilleans have been one of the ethnic groups at the bottom of the social, political, and economic hierarchy. For long periods, Panamanian Afro-Antilleans perceived themselves, and were perceived by Panamanians of other ethnic groups, as temporary migrants. Because of the isolation that they were forced to endure both inside and outside the Canal Zone, and on the banana plantations in Bocas del Toro Province, Afro-Antilleans were able to maintain many of their distinctive customs and traditions (language, religious traditions, and architecture, among others). This distinctiveness was viewed by mainstream Panamanian society as a problem, particularly since many Afro-Antilleans were determined to maintain their "British" way of life.

Indigenous peoples in Panama represent approximately 10% of the total population. The Ngöbe are the largest indigenous group (169,130 in 2000). Until the end of the 19th century, most Ngöbe were able to have a livelihood exclusively based on slash-and-burn agriculture (maize, beans, bananas, tubers), complemented by hunting, fishing and gathering. From the 1930s, wage labor became an increasingly important supplement to subsistence activities. The Ngöbe complain that they have received little governmental attention to their problems. Currently, two of the most pressing issues faced by this group include their

struggle to establish clear boundaries for their *comarca* (reserve) and their increasing poverty.

Perhaps the best-known indigenous group in Panama is the Kuna (61,707 in 2000). Historically, the Kuna have negotiated from a position of strength in relationship to the Panamanian government, and have been able to achieve some level of recognition by the nation-state. When Panama gained independence, the state led campaigns of Christianization and “civilization,” bringing with it western transformations were not welcomed by the Kuna. In 1923, Kuna leaders Nele Kantule and Cimral Colman organized to prevent any non-Kuna person from living in Kuna territory, and later led an uprising against the Panamanian government in 1925. As a result, they were granted the status of a Kuna-run semi-autonomous territory in 1938, becoming the first legally recognized *comarca* in Panama. Since then, the Kuna have become the trademark of Panamanian tourism, particularly because of their culture, their land-base, and the famous *molás* (an artwork of fabric appliqué made by women).

Politically, Panama has had one of the most resilient military periods in Latin America, from 1968 to 1989. One of the most prominent leaders in the history of this period is General Omar Torrijos. Although he was never the formal president of the country, Torrijos was the *de facto* leader from 1968 to 1981. Torrijos (a Lieutenant Colonel at the time) was part of a military junta that organized a coup d'état on October 11, 1968 against Dr. Arnulfo Arias during his third presidential period. Colonel José María Pinilla and Colonel Bolívar Urrutia formed this Provisional Junta, with Torrijos being the most prominent figure. This was the first time that there was a successful military uprising against a civil government in the history of the republic. The ideological notions presented by the Junta were the cleaning up of the public administration and the rejection of communism. Engineer Demetrio Basilio Lakas and Arturo Sucre were chosen as the president and vice president, respectively, of the new government. On March 11, 1969, Omar Torrijos was named General of the Republic. A new constitution, replacing the Constitution of 1946, was ratified in 1972. Under this constitution, Torrijos became Maximum Leader of the Panamanian Revolution, which gave him almost unlimited powers during Lakas's six-year presidential period. Torrijos was named coordinator of the public administration and external relations of the Republic.

Torrijos governed the country with a very informal approach and an ideology leaning to the left. Under his leadership, the state became an investor in projects such as sugar cane refineries, food and coffee factories, and cement factories, among others. Part of Torrijos's strategy of modernization was to create industries in both urban and rural areas. Schools, electricity, sewage, and water facilities were built or improved under his regime. Indigenous populations were particularly targeted for assistance during his presidency, not a popular policy in the eyes of non-indigenous groups. Simultaneously, Torrijos implemented policies conducive to maintaining a romanticized peasant past as the dominant representation of Panamanian folklore and national identity. These policies were the result of decades of emphasis by the Latino upper classes upon the connection between Panama and Hispanic America.

In regard to foreign policy, Torrijos supported socialist movements such as the Sandinistas and the Cuban revolution (although his common motto was “Neither with the right nor with the left, with Panama!”). The United States government viewed this support negatively. In addition, Torrijos applied aggressive diplomacy with the goal of bringing the international community to work for Panama's causes and to negotiate the return of the Panama Canal to Panamanian hands. On February 7, 1974, U.S. Secretary of State Henry Kissinger and Juan Antonio Tack signed the Declaration of the Eight Points. This declaration established the basic principles of the new contractual relationship between the two countries, including the elimination of the concept of perpetuity, the end of the U.S. jurisdiction in Panamanian territory, the return of the Canal Zone to Panama, and access by Panama to the benefits derived from the operation of the Canal, among others. After long and complicated negotiations, the United States and Panama signed the new Treaty of the Panama Canal on September 7, 1977, at the OEA in Washington, as well as the Treaty of Permanent Neutrality and Functioning of the Panama Canal, better known as the Torrijos-Carter Treaties. This treaty recognized the sovereignty of Panama over the Canal Zone and established that the United States would return the rights to operate the Canal in its entirety to Panama, along with all lands and facilities still remaining under U.S. control, on December 31, 1999. It also guaranteed that, in the interim, the administration of the Canal was to be conducted

by a U.S. governmental agency whose board was to be composed of United States and Panamanian members. Both nations compromised to protect and defend the Canal, and in terms of economic benefits, they were to revert to Panama 60% of the land and infrastructure of the Canal area. On December 31, 1999, all remaining property was turned over to Panama and administered by the Inter-Oceanic Regional Authority. On December 31, 1999, elected president Mireya Moscoso officially received the Panama Canal from United States President William Clinton.

In 1978, Torrijos was offered the presidency of Panama. He declined and conceded the presidency to Aristides Royo and the vice-presidency to Ricardo de la Espriella. Torrijos's death in a suspicious plane accident on July 31, 1981 produced instability in Royo's government. His presidency lasted for one more year after the death of Torrijos. After this, there was a strong period of instability in the country, which brought to the presidency seven presidents in seven years. The most notorious leader in this period was General Manuel Antonio Noriega who took control of the National Guard and the country in 1983. A period of brutal political and civil repression followed. The Panamanian National Police, instituted in the 1940s and highly militarized, was transformed into the *Guardia Nacional* in 1953. Noriega renamed the guard the Panamanian Defense Forces (PDF) in 1983, and used it to maintain a highly repressive regime. Noriega's policies led to the invasion of Panama by United States military forces in December 1989, and the elimination of the PDF.

Economically, the main revenues for Panama have generally come from the Panama Canal, the Duty Free Zone, and banana production. Since the 1990s, one of the most important (and currently, the most important) income earner for the country has been tourism. Tourism has produced a fundamental turnabout in the political policies of the country. Following the end of the military dictatorship of General Manuel Noriega, Presidents Guillermo Endara (1990–1994) and Ernesto Pérez Balladares (1994–1999) sought to develop tourism (more specifically ethno- and eco-tourism) as one of the most important industries of the country. Endara declared tourism a national priority for the country, and Pérez Balladares imposed laws that facilitated foreign investment related to tourism. The most current numbers are available for the year 2003. In that year, tourism generated more earnings for Panama (\$805 million) than the Panama Canal

(\$690.3 million), the Canal Zone (\$487.7 million) and banana production. This amount represents a growth in tourism income of 18.6% in relationship to the year 2002 (\$678.8 million). As a result of this focus on tourism, marginalized groups (such as Afro-Antilleans and some indigenous groups) have had some access to a more important presence in the national context.

Pantheism may be defined as the doctrine that God is coextensive with and identical to all things. Clearly distinct from both atheism (the belief that there is no God) and panentheism (the belief that all things are suffused with God's essence, but are distinct from God), pantheism generally arises only in cultures with a fully developed religious life.

Pantheism arises from two related tendencies. The first is a fervent religious spirit that is inclined to see divinity as a universal phenomenon, necessarily infused within all things. The second is an essentially philosophical desire to uncover some sense of unity, a common thread that connects all things and binds them to each other. Both elements must be present in order for pantheism to take firm root.

Vedic Pantheism

Pantheism may be roughly divided into eastern and western varieties. Vedic pantheism takes as its point of

departure a critique of polytheism. The Vedic pantheon of many gods gradually transformed into a single entity, or (more accurately) a single concept: the notion of Brahmin. Brahmin represents that which does not change, is perfectly unified and univocal, without limit, and non-definable. While the world appears to be in a state of constant flux and change, it is the idea of Brahmin that provides a permanent unchanging substrate upon which these appearances depend. Because change implies imperfection—and because there must be some perfect being, entity, or higher order—the twin conclusions are drawn that, first, there must be something above and beyond the material world, and, second, that the material world itself must be an illusion. To claim otherwise would be to admit the possibility that imperfection could have inherent and hence independent reality, and consequently that nothing would be permanent. If Brahmin were divided into the perfect and the imperfect, then it would obviously be no longer permanent, since imperfect things pass away. This is impossible, because Brahmin by its very nature endures and persists through the apparent changes that seem to occur in the world.

It follows, then, that change does not really occur. Change is an illusion. This follows necessarily from the basic premises. If all truly is one, and all is united, and all is perfect, then Brahmin is all and all is Brahmin. Brahmin cannot change, because Brahmin is perfect and change is a sign of imperfection. If change is real, then change is part of Brahmin, since what is real is Brahmin. This would mean that Brahmin is changeable and consequently subject to imperfection. To the Vedic mind, this is anathema. Ordinary sense experience is characterized by illusion, or *maya*. The mystical and contemplative practices prescribed are intended to aid the worshipper in overcoming *maya* and coming to a true understanding of the oneness of *Brahmin*.

Western Pantheism

The sixth-century B.C. philosophical monism of such pre-Socratic philosophers as Parmenides and his pupil Zeno (who illustrated his master's points by means of his eponymous paradoxes) are arguably pantheistic, since they maintained as their fundamental truth that "All is One." Parmenides and Zeno claimed that knowledge could only be of things that do not change; otherwise, one would find oneself in

the apparently absurd position of claiming a given standard of knowledge on one day, only to discard it the next in favor of a different standard. Following a line of reasoning that resembles the Vedic, they maintained that since knowledge must be of things that do not change, and knowledge is possible, then there must be something that does not change. Because that which does not change cannot become something other than what it is, it must be One, entire unto itself, without parts, and unknowable on its own terms. Parmenides and Zeno, like the Vedic, deal in appearances whose reality they deny while affirming the ultimate reality of something that is unified, perfect, and One.

Earlier materialist pre-Socratics (like Thales, Anaximander, and his disciple Anaximenes) had asserted the primacy of one or another of the four Greek elements (earth, water, fire, and air), but had stopped short of declaring the others illusory. Theirs is more a reductionist philosophy than a pantheism.

The apparent pantheism of certain early Greek monists (like Parmenides and Zeno) stands in stark contrast to that of other pre-Socratics like Heraclitus, the so-called "weeping philosopher," who so despaired of finding anything like a permanent, unchanging substrate that he identified fire as the primary element. Fire, of course, is both ever-changing and something that must destroy in order to keep itself in existence.

The best known and most widely recognized western pantheist is Baruch Spinoza (1632–1677). Spinoza saw the miseries of human existence, and was committed to finding some permanent source of goodness that might serve as a basis for human happiness and flourishing. Spinoza maintained that such a basis would have to be found in something that is capable of completely filling the human mind. He further argued that such a standard could only be met by the recognition that the mind is one with nature (i.e., the world that appears to mind and presents itself as something external and extrinsic to mind). By recognizing its intimate connection with nature, the mind can overcome human misery since it will recognize its place within the totality of creation. Having grasped its place in the grand scheme of things, and come to peace with its limited extent and efficacy, the human mind can come to understand the necessity of the place it occupies, see that things could not be other than they are, and accept its lot in life without complaint or recrimination.

Many other forms and variants of pantheism exist in the western tradition. Indeed, the word “pantheist” was not used until 1705, when it was apparently coined by John Toland. Ironically, it was through the word’s use as a term of derision by one of Toland’s critics that “pantheist” and later “pantheism” entered into general usage. The 18th century saw a rise in pantheism in Europe as intellectual elites struggled to reconcile matters of faith with what were widely perceived the logically untenable demands of faith. Pantheism offered an attractive middle ground for those reluctant to accept Church doctrine, yet unwilling to embrace atheism.

PARALINGUISTIC COMMUNICATION

Paralanguage refers to verbal communications that have meaning but are not part of the system of words and grammatical rules we call language. Paralanguage includes such elements as pitch, amplitude, rate, and voice quality. Laughter, imitative speech, and prosody are also forms of paralanguage. Paralanguage emphasizes the fact that people convey meaning not only in what they say, but also in how they say it.

Paralinguistics is a crucial component in all human communication. In any verbal interaction, we employ sets of culturally constituted codes to make a series of inferential judgments that interpret what is being said. These interpretations occur at several levels, including linguistic and paralinguistic, as well as kinesic, musical, interactional and others.

Paralinguistic communication often operates as a metamessage to alert communicants as to how to interpret a message. For example, in American English, a simple change in tone and stress can determine

whether a linguistic statement such as “What a lovely dress” is a compliment or an insult. Paralinguistic elements are also used to initiate and sustain verbal interaction.

Paralanguage is believed by many scientists to be a survival of the gesture-call systems used by other primates to indicate current states of being, such as contentment, hunger, irritability, restlessness, sleepiness, and so forth. Yet, although many paralinguistic elements are universal, the ways they are used are culturally defined. For example, American English speakers use a sing-song rhythm to indicate mockery, but this rhythm is normative in many South Asian languages. Some Mayan Tzeltal speakers use a creaky voice for complaints and commiserations, and falsetto for polite greetings and formal conversation.

Moreover, verbal elements that are used as paralinguistic features in one speech community may be linguistic elements in another. Pitch is primarily a paralinguistic feature for most English speakers, but it is primarily a grammatical feature in many Asian speech communities.

The nature and breadth of paralinguistic communication varies not only across cultures but across modes of communication. The choice of medium used for communication—speaking, writing, photography, motion picture—enables and constrains the capacity of a message to carry paralinguistic cues. Face-to-face communication has the highest paralinguistic density. Telephone and recorded conversation carry verbal paralanguage but miss paralinguistic-kinesic pairings. Written text carries the least paralinguistic information, although there are creative alternatives such as the “emoticons” widely used in e-mail to indicate emotional states.

The significance of how a loss of paralinguistic information can affect meaning has been emphasized in studies of written communication such as court transcription or journalism. Although both forms of writing lay great emphasis on quotation, failure to capture nuances of speech can cause a statement to take on a very different meaning. The classic example is the cry of anger and incredulity by a crime suspect, “I did it?” being recorded as a confession: “I did it.”

Defining the boundaries of paralinguistic communication is difficult. Paralinguistic communication is closely related to kinesic communication which includes gesture, body posture, and other nonverbal forms of communication. Often, particular gestures are routinely accompanied by particular sounds;

such pairings may not have the same meanings when separated.

Sometimes it is even difficult to clearly differentiate the paralinguistic from the linguistic. English uses pitch both grammatically (as when we signal a question) and to signal emotional meaning. While many forms of emphasis are outside of the language system, others, like contrastive stress (*This is the one*) and question intonation (*Is this the one?*) are grammatical in nature. Some verbal expressions intended to indicate natural states—in English, for example, the sounds we indicate by *uh-oh*, *whew* or *ouch*—are so conventionalized as to be part of the lexicon.

Paralinguistic communication is also sometimes distinguished from extralinguistic communication, which refers to oral noises like teeth chattering or yawning. Such verbal communications are meaningful, because they index physical states, but their meaning is involuntary. Likewise, changes in voice caused by old age or by nasal congestion would be defined as extralinguistic.

One problem with the distinction between paralinguistic and extralinguistic communication is that it relies on the capacity of the observer to determine whether a communicative act is intentional or natural. This is especially tricky because many paralinguistic communications are mimetic—that is, they imitate natural states. An English speaker may be unable to articulate the difference between /p/ and /b/ because she has a cold, or she may be intentionally confusing the two to sound as if she has a cold.

Although paralinguage has never received as much scholarly attention or popular interest as kinesics, the significance of paralinguage has had a far-reaching impact on linguistic anthropology. Among other things, paralinguistic evidence contributed to the rise of the ethnography of communication, which takes speech communities, speech acts, and “ways of speaking”—rather than languages—as its units of analysis. In addition, there have been a series of creative efforts by anthropologists to capture paralinguistic elements in their ethnographic descriptions of speech.

Because paralinguage is so intimately intertwined with linguistic, kinesic, and other levels of communication, it is rarely studied by itself. But paralinguistic phenomena remain of key interest to anthropological linguistics.

PARALANGUAGE

Paralanguage is the use of a certain manner of speech to communicate particular meanings. It goes beyond the spoken word. It consists of vocalizations that are not words. Through paralanguage, people reveal their emotions to one another, either voluntarily or involuntarily. Paralanguage is related to body language, in that it is a way of communicating without using conventional words.

Paralanguage is an important part of human communication. It includes voice quality, which is made up of volume, pitch, and rate of speech. It also includes pauses and non-words such as *uh*, *er*, and *um*. We can often tell from the sound of a person's voice whether the speaker is sick, sleepy, drunk, or depressed. We have come to know what certain sounds of paralanguage mean, such as *ouch!*, *huh?* and *hmmm*. However, these sounds vary from culture to culture, so one has to be careful when trying to communicate with those of another culture.

Paralanguage has been determined to be an important part of the communication between infants and their mothers. Of course, babies can't use words, so mothers are prone to communicate with their infants through use of comforting sounds rather than actual words. It's also thought to be an important means of communication between adults in the areas of intimacy and sexuality.

During their study of paralanguage, scientists have used several types of cameras, recording

devices, and other electronic instruments to pick up and record the sounds of paralinguage. Sensitive microphones can pick up differences in voice inflections and tonal qualities of the voice.

Consumer researchers have studied the shopping behavior of customers using paralinguage. Specially designed cameras and other recording instruments have picked up on the interest consumers have shown via paralinguage in certain products in the market place. Radio and television journalists have learned to modulate their voices in appropriate ways when giving a report. They need to appear objective and distant from the story, with the result that they often speak unnaturally.

Communication specialists are able to train people to have control over their paralinguage in order to modify their relations with others. Actors, singers, and public speakers also learn to correct, change, and modify their speech and manner. Thus, they are able to make a better impression on their listeners.

PARK, ROBERT EZRA (1864–1944)

Born on February 14, 1864, in Harveyville, PA, and raised in Minnesota, Robert Ezra Park graduated from the University of Michigan, where he studied with the philosopher John Dewey. Concerned with social issues of his day, especially racial problems in urban settings, Park became a newspaper reporter, and eventually resided in Chicago. In 1898, he entered Harvard University where he studied with William James. After earning an M.A., he traveled to Germany, where he heard lectures from Georg Simmel on sociology and studied with the philosopher Wilhelm Windelband. After completing his doctoral dissertation, he taught at Harvard before being invited by Booker T. Washington to affiliate with the Tuskegee Institute in order to investigate racial issues in the South. In 1914, Park joined the University of Chicago's Department of Sociology, where he remained until 1936. After retiring, he moved to Fisk University, where he continued teaching until the end of his life.

Through his publications and his numerous students, Park became widely known, serving as president of the American Sociology Society, as a member of the Social Science Research Council, and as president of the Chicago Urban League. He died at Nashville, Tennessee on February 7, 1944.

During Park's time in Chicago, the University's Department of Sociology began to focus on the surrounding urban environment as a laboratory for social research. Along with his faculty colleagues, Ernest Burgess, Louis Wirth, Homer Hoyt, and numerous students, Park developed an orientation to urban ecology that became known as the "Chicago School of Sociology."

His essay "The City: Suggestions for the Investigation of Human Behavior in the Urban Environment," originally published in 1915, served as the introductory chapter for the influential essays collected in *The City* (1925). Park's other essays in the volume included "The Natural History of the Newspaper," "Community Organization and Juvenile Delinquency," "Community Organization and the Romantic Temper," "Magic, Mentality, and City Life," and "The Mind of the Hobo: Reflections upon the Relation Between Mentality and Locomotion."

Through his studies in Chicago and his visits to cities around the world, Park developed his concept of "natural areas." For Park, the relationship between individuals and groups within such areas involved mobility among urban spaces and across social classes. Mobility, in turn, often resulted in social disorganization and individualization, as formulated in his famous article "Human Migration and the Marginal Man" (1928). Throughout his career, Park related his theories about assimilation, community structure, and mobility to the plight of ethnic populations.

PARTICIPANT-OBSERVATION

Often described as immersion in a culture, participant-observation is the principal methodological component of ethnographic fieldwork. The researcher watches people and their activities in the social situation under study, gradually increasing participation in the culture as a check on observations. In turn, continuing observation allows for greater and more accurate participation. As the process proceeds, the ethnographer is able to write field notes as a cultural participant as well as an observer, fostering richness and complexity in the qualitative and quantitative data collected and analyzed. Participant-observation may occur in projects that range in time from weeks to years with the average as one to two years. Any physical setting can serve as the location for participant-observation. Cultural anthropologists have studied patients in U.S. hospital rooms, multi-ethnic neighborhoods in the Middle East, and Inuit subsistence practices.

As a strategy, participant-observation is particularly useful if the research topics are usually hidden from outsiders such as family life or religious activities, if the interest is in behavior that is observable within daily life, if the group is limited by size and/or location as in a specific case study, and if emphasis is on understanding meaning from the emic or insiders' point of view. Participant-observation is not appropriate for studies with large populations or when precise causal relationships between limited variables are sought. Thus, the approach typically is not deductive in design or based on hypothesis testing models.

Participant-observation helps researchers refine skills in the native language, facilitating appropriate interviewing, which is the other primary ethnographic fieldwork method. Since participant-observation enables ethnographers to understand interview, survey, and observational data, it enhances research validity. It also allows the fieldworker gradually to become part of the cultural scene, thereby minimizing people's attempts to modify behavior from their ordinary routine. Although participant-observation moves a researcher from a position outside a culture to that of an insider, it does not eliminate all cultural barriers. The amount of insider knowledge that can be gained through participant-observation varies from project to project depending on the extent of

active complete participation that is possible. During ethnographic fieldwork, the participant-observer also will experience changing emotional states from initial excitement to culture shock and from contentment to despair and back again as the work proceeds. These emotions too are noted in the field diary as part of the data record.

The development of participant-observation in anthropology is usually attributed to the late 19th and early 20th century change from "armchair" research to "fieldwork" and direct data collection by researchers. Bronislaw Malinowski's fieldwork in the Trobriand Islands is recognized as emblematic of this new form of data collection, given his attempt to describe in detail the everyday life of people, rather than reconstructing past culture or fitting them into a preexisting evolutionary framework. The key change was a new paradigm in which empiricism was crucial. There is also a tradition in sociology, dating back to the 1920s and 1930s, which uses the method of participant-observation. Recently, educational researchers, and others in the humanities and social sciences, also have utilized participant-observation.

PASCAL, BLAISE (1623–1672)

Pascal was a polymath who became a major figure in religious thought and polemics, mathematics, theoretical physics, philosophy, and French literature, along with the design of public transport. There are surprising connections between different parts of his thought. For example, his mathematical ideas on probability are used in a famous "proof" of the existence of God. The status of this proof, known as Pascal's wager, should not be exaggerated. It was probably intended

BLAISE PASCAL
(From the painting by Philippe de Champaigne.)

Source: Courtesy of the Library of Congress.

as a way of grounding, or reinforcing faith rather than as the equivalent of a metaphysical-logical deduction of God's existence. In Pascal's wager we should believe in God because it brings us happiness to hope for an eternity of bliss after this life. If the belief is false, we will not lose anything, and if it is correct we make it less likely that we will be punished with an eternity of torment likely to result from failing to accept God.

The argument for God from a form of probability may have survived Enlightenment skepticism better than the intended certainty of metaphysical proofs. What may be more important about the wager is that it expresses the collapse of a metaphysical-theological structure of thought in which God's existence seems tied up with the existence of nature. In this worldview, humanity itself has clearly defined natural and divine purposes.

Pascal is among the key figures in establishing another view of humanity, which underlies the emergence of modern social science. Pascal's questioning of the old commonsense anthropology partly came

from the Copernican Revolution in Science, and partly from an insistence on a very austere form of Catholic Christianity known as Jansenism. Jansenism was rooted in commentaries on St. Augustine by the Belgian Bishop Cornelius Jansenius, which came to be regarded as heretical by the Vatican. Jansenius, and his followers, emphasized the elements of pre-destination, the fallen nature of humanity and absolutist moral rigor in Augustine. It seems close to Calvinistic Protestantism, but the Jansenists were keen to deny this (as Pascal does in "Writings on Grace"). The convent and school of Port-Royal, in Paris, became a center of Jansenist religious thought, as well as a great center of education (Jean Racine was a student there) and philosophy (Pierre Nicole and others). Pascal had family connections with Port-Royal and became a Jansenist himself. He joined in a battle against the Jesuits, whom the Jansenists considered lax in application of principles, in the polemical-literary work, *Letters Written to a Provincial*.

The Jansenists were operating in a political environment where at first the French monarchy found them useful in combating the influence of the Jesuits and the Papacy in France, but they were later repressed when the conflict with Rome started to threaten the monarchy.

The currents of Pascal's life and work come together in his central achievement *Pensées* ("Thoughts," but translations always leave the French title). Pascal's Wager appears there in a series of fragments that mix biblical interpretation with compressed meditations on philosophy and the condition of humanity. Pascal's Wager itself rests on Pascal's view of humanity as lost without God, and as marked by the loss of God, since God is absent from nature and the universe. After Copernicus, the universe lacks a center. It has become an eternal sphere without a center. In comparison to the infinite spaces of the universe of modern science, humans can be no more than thinking reeds. Humans have grandeur, but it is lost grandeur because of their fallen nature. We belong with God, but original sin separates us from the happiness of union. Not only are we weak in relation to physical nature, our lives lack substance. Someone who spends half his life dreaming that he is a king is as happy as that king, who might be dreaming that he is one of his lowly subjects.

The idea that life may be no more than a dream and that God is absent from the natural universe can be found in Pascal's predecessor René Descartes, but

Pascal attacked Descartes's philosophy as useless and ineffective. Descartes's search for pure foundations to knowledge, in order to overcome skepticism, was considered contradictory by Pascal. Reason cannot justify itself, because we can always keep asking, what is the reason for this reason? According to Pascal, there must be "reasons of the heart" at the origins of all knowledge. There may be an element of religious mysticism here, but less than the phrase suggests. "Reasons of the heart" refers to our capacity to create first principles, such as mathematical axioms. There is no absolute justification for such principles, but we must assume them in order to have knowledge or science of any kind. The skeptical and hypothetical-intuitive spirit is expressed in thoughts on politics and society. The dream of being king already hints at the unreality of legal sovereignty. Pascal regarded all human laws, including those upholding state sovereignty, as fictional. Their only foundation is in force, so we cannot regard them as expressions of natural-theological right. The arbitrariness of law, its lack of intrinsic injustice, is shown in the great variations of law on either side of a changeable border, between humans living in one state and humans living in another state. We cannot regard human societies as conditioned by the ethics and justice of a system of natural right. Our laws themselves emerge from the vanity and self-interest of humans who are driven by the constant urge to have more grandeur than other humans. The search for grandeur is an expression of the lost grandeur of fallen humanity. The consequence is that societies are grounded on the drive for status, prestige, and recognition. These thoughts evidently parallel those of Niccolò Machiavelli and Thomas Hobbes on the tendency for humans to seek self-advantage rather than virtue, and anticipate political economy. They made a deep impression on Alexis de Tocqueville to the extent that they are essential to understanding his political and social thought. Pascal's thought also clearly anticipates Jean-Jacques Rousseau's views of the natural, substituting for God, and the social. This can be seen in *Pensées*, but also the "Writings on Grace," where Pascal establishes the general will of God, in which God wishes to save all humans. Evidently this general will cannot be applied absolutely since all humans are fallen, but it provides grounds for saving an elect few. More recently the cultural and social thought of Slavoj Žižek and Jacques Derrida has included significant considerations on Pascal; his influence must be

recognized wherever Rousseau and de Tocqueville have left a mark. He is at the origin of modern anthropology in the broadest sense.

Patriarchy is a theory about social organization that refers to a system of male authority that is seen to oppress women through its social, political, and economic institutions. In a patriarchal society, power rests in the hands of men, who have a greater access to, and control of, resources and rewards both in the domestic and non-domestic spheres. Wives and children depend on the men and inheritance is through the male line.

Patriarchy is to be distinguished from patrilineality, a system in which one belongs to the father's lineage, and patrilocality, a social practice in which newlyweds live with or near the family of the husband. Many feminist writers view patriarchy as the root of the formation of most modern society.

Second Wave feminists (a stage in feminism which started in the late 1960s) were united by the theory of patriarchy. Patriarchal relations were assumed to be structural and operating at an institutional level. Different schools of feminist thought defined patriarchy in various ways. Perhaps the radical view is the one that has received the most publicity: patriarchy is a medium that oppresses women and has operated through the family across history. Society is based on a hierarchy that privileges masculinity and devalues femininity.

Matriarchy has often been presented as the "real answer" to patriarchy. The earliest study of matriarchy was published by Johann Jakob Bachofen in

1861 (*Das Mutterrecht*, The Mother Right), and he viewed matriarchy as an inferior form of societal organization. However, no matriarchies exist in the present, and primary sources recounting them are lacking, and thus the idea of female-dominated societies is generally discounted. In the same year that *Das Mutterrecht* was published, Henry Summer Maine published *Ancient Law*, which sought to show that originally all human groups were organized on the patriarchal model. Patriarchal societies exist in practice as well as in theory.

It should be noted that societies previously described as matriarchal (for example, the Iroquois) turned out to be matrilineal, even if Iroquois women wielded substantial power. There have been many attempts to label past societies as matriarchal, most notably work by Marija Gimbutas. She hypothesized that much of what she calls “Old Europe” was blissfully matriarchal until the arrival of patriarchal societies in the Bronze Age (the Kurgan hypothesis). Various archaeological investigations have not confirmed this hypothesis and available evidence has so far failed to support an ancient matriarchal society.

In contrast, archaeology has unearthed various examples of patriarchal societies, for example, the Romans. Evidence clearly shows that the *pater familias*, the head of the family, enjoyed absolute authority and had the power of life and death over children and slaves. Women passed on their dowry under the authority of the *pater familias* of the husband’s family.

Patriarchy is generally accompanied by notions of a strict binary gender system. However, the situation is often more fluid, for example, the Tuareg people, although patriarchal in structure, still practice descent through the female line, and females enjoy a certain degree of respect and freedom, although under the supervision of men.

PATTERSON, FRANCINE G.

The art of communication has been practiced by many people in many different ways. However, one individual by the name of Francine Patterson has focused on a unique study that has received national and international attention. Patterson has chosen to make her professional life a study of communicating with gorillas and doing what she can to prevent their extinction in this world. Her interest in this activity began as a graduate student at Stanford University, where she received her Ph.D. degree in Developmental Psychology. It has continued since her university days at Stanford, and resulted in the longest study of interspecies communication that exists so far.

Patterson’s philosophy suggests that we can learn much from communicating with gorillas, and that it will be beneficial to them, and to ourselves as well, if such efforts are made. Her work is especially beneficial to linguistic scholars who are attempting to study the links between species. However, in addition to studying communications with gorillas she is also interested in preserving their presence in the world for all to enjoy and to study. Patterson’s efforts to study and to maintain the existence of the gorillas have received recognition. She has been able to publish a number of books dealing with gorillas and has received various noteworthy awards. In 1997 she was chosen as a Kilby Foundation Laureate by the Gorilla Foundation in honor of her long and continuous efforts regarding primate linguistic abilities.

Today, she continues her work by serving as Chairman of the Board for the Gorilla Foundation and is working toward the accomplishment of a preserve in Hawaii for gorillas. She is also a Board member of ApeNet, which is a group of foundations interested in studying communication regarding these animals. Patterson has also found time to serve as Editor in Chief of “Gorilla,” a Foundation journal. As you would

expect, she is the author of a number of books that provide useful information about her specialty.

PEASANTS

In his seminal book, *Peasants*, Eric Wolf explains that peasants are “those large segments of mankind which stand midway between the primitive tribe and industrial society.” Wolf’s book is a tour-de-force explanation of who peasants are, as well as a 1960s state-of-the-art statement about what had become one of the more important classificatory categories in anthropology.

Peasants are generally considered to be farmers who sell their surplus in the market. How this surplus enters the market, conceived of broadly, can be in the form of hard goods directed at a marketplace, the payment of rent to a landlord, the payment of taxes to the government, or various combinations of these. Peasants are

semi-self-sufficient, meaning they reproduce most but not all of their subsistence needs. In order to fulfill their basic needs they enter the marketplace, where they sell their surplus agricultural products and other crafts produced by members of the household. Peasants are members of states that, through various forms of coercion, also draw them into capitalist markets. However, as Wolf notes, peasants tend to be conservative and resist proletarianization.

From the beginning, anthropological studies of peasants have been concerned with the description of peasants—their life-ways and economic practices—and with the utility of the category itself. Since

Redfield’s description of peasant life in Tepoztlán, Mexico, the concept has undergone numerous changes and continues to prompt new theoretical debates. Redfield’s ethnographic work in central Mexico and later in Yucatan awkwardly identifies his subjects not as peasants but as tribal people. He locates them on a primitive-civilized continuum that often overlooks their relationship to the state and to the capitalist economy. His student, Sol Tax, was one of the first anthropologists to correct this perception of indigenous people in Mexico and Guatemala by making the argument that they were not tribal people but farmers and members of states. Moreover, he recognized that the basic unit of production is at the level of household, not individual. Such observations anticipated the later theoretical and analytical work of anthropologists, such as Enrique Mayer, June Nash, James Scott, and Eric Wolf.

Peasants did not become a major focus of anthropological study until after World War II, when it was apparent that “primitive” and “tribal” were inadequate classificatory terms for many peoples around the globe. The interest in peasants related to the emerging crisis that the primary object of anthropological study, the primitive, was disappearing, and to the direction anthropological research had turned in order to explain this cultural change and the relationship of the state to “traditional” peoples. After the war, there was greater awareness on the part of anthropologists to conceive of all people as part of states and global economic systems, not as isolated groups.

As long as states have existed, so have peasants. Most anthropological research on peasant economics and on peasants as members of states has been influenced by Marxist theoretical perspectives, namely, that of Lenin and Chayanov. For Marx and his later followers, peasants are problematic. Because of their conservative tendencies to preserve their lifestyle, it was not clear with whom they would ally themselves—the bourgeoisie or the proletariat. Marx believed that eventually capitalism would destroy the peasant lifestyle, since it is incompatible with industrialization, and that most peasants would become proletarians.

Lenin postulated that industrialization could come from within an agrarian-based society through labor surpluses within the rural population and through market surpluses, which were necessary to feed the growing proletariat. As land became scarcer—something the state could control by encouraging privatization of land and altering traditional land tenancy systems—more peasants would be forced into the labor market. However, as the proletariat increased, the demand for food products would increase, which could only happen with the further capitalization of agriculture. Hence, while a few rich peasants transformed into landowners who hired wage-laborers, most peasants would become the laborers who worked for wages. Effectively, the household-based economic unit of peasants would be replaced by a class-based industrial system, where individuals sold their labor.

What Lenin did not recognize was that such transitions to capitalistic industrial farms were not compatible to all political and economic contexts. In Latin America, states have given concessions to peasants—land itself, support of communal land tenure systems, price protection of subsistence crops—which allowed them to maintain their lifestyle, in order to gain their political support. Even though land ownership continued to consolidate in places like Mexico and Southeast Asia, landlords still provided their workers with plots of land for them to cultivate. This inhibited the complete proletarianization of the peasantry. In Asia and Korea, for example, the landlord class, which had the potential to transform the peasant economy into a wage-based one, was destroyed by their Japanese occupiers, allowing peasants to maintain their household-based economic system.

Chayanov challenged Lenin's perspectives on peasants. He believed that Lenin missed the true nature of peasants. For example, he contended that peasants

were not per se opposed to or incompatible with capitalism. They provided surplus labor at times and sold their surplus products in the market. Lenin's theory is flawed because it disregarded the ways in which peasants economically maintained their households. According to Chayanov, the peasant household was not capitalistic, but based exchange on use value. Families work to provide for a basic livelihood, which did not mean they maximized production or were profit oriented. Because of this, individual peasants and peasant households do not behave like proletarians and capitalistic firms. Instead, they balance labor with consumption. Household members work to fulfill needs, but because of the drudgery of the work, they do not strive to increase surplus much beyond basic needs. Fewer working members of the household in relation to non-able-bodied workers meant that they work more than those in households where the worker to nonworker ratio was less. Furthermore, this household-based unit of production is incompatible with capitalism, because in order to maintain their basic minimum subsistence level, members in a peasant household will produce more, even if doing so results in lower prices. In contrast, this practice would ruin the capitalist firm.

Chayanov's theories depend on the relative scarcity of land and lack of other employment options to absorb surplus labor. Also, they fail to take into consideration local cultural conditions about what constitutes appropriate consumption needs, nor do they consider the broader coercive mechanism of states and capitalistic markets. His theories, however, have inspired anthropologists. Marshall Sahlins began to think about domestic modes of production, and Eric Wolf began to think about the cultural conditions in which peasants replace those things necessary to their production and subsistence. June Nash has used Chayanovian theory to look at how capitalism has challenged domestic production in peasant households and contributed to gender conflicts.

Both Lenin and Chayanov challenged anthropologists to think about peasants' relationship to the state. After World War II, a concern of First-World countries such as the United States was to help Third-World countries in Latin America, Asia, and Africa to develop into comparable First-World countries. Anthropologists not only described the composition, and economic and cultural conditions, of peasant households, they were also concerned with how economic developments would positively and negatively

affect peasants. When anthropologists observed that in societies with large peasant populations, the economic conditions did not improve—in fact, often worsened—they questioned the utility of development policies directed at these populations. They identified that peasants were drawn into exploitative systems, which undermined their traditional economic and cultural bases, while simultaneously incorporating them into a larger, global capitalist system in which their labor was further devalued and resulting in a greater market dependence.

Because such dire structural—economic and political—conditions have contributed to peasant revolts, peasant-supported revolutions, and other forms of resistance, anthropologists have studied what makes peasants engage in various forms of resistance, and why, more often than not, this resistance has not led to social and political change. Eric Wolf's 1969 book, *Peasant Wars of the Twentieth Century*, outlines peasant participation in the main revolutions of the 20th century—Mexico, Russia, and others—to illustrate the conservativeness of peasants and the difficulty for peasant-based revolutions to lead toward meaningful social change. Peasants revolted, but usually in order to restore the status quo. In places where revolution led to real social change, Wolf notes that it is not the peasantry, but the proletariat, intellectual, and surviving bourgeoisie classes that guide the new direction that a country takes. Even so, this does not mean that peasants are passive and have no agency to resist. James Scott has contributed most to this line of research. Drawing on theories of hegemony and power, Scott's ethnographic work highlights the everyday forms of resistance of peasants in Southeast Asia. His influential research shows how peasants find the means to resist the state and landlords, from foot-dragging to sabotaging harvests, and construct critical counter-discourses that evade repressive policies and mechanisms of control.

Contemporary anthropological studies of peasants have gone in three primary directions: the continued existence of peasants, the demise of peasants, and the emergence of the term peasant as a category of self-identification and political identity. Enrique Mayer is the leading proponent of the belief that peasants persist and are able to reproduce their ways of life, despite the effects of late-capitalism and neoliberal policies. He argues that theoretical models and ideal typologies of peasants can be misleading, and are not reflected in the lived realities of those people. Instead of arguing that

recent and current economic and political conditions have undermined peasants and caused them to disappear, he shows how Peruvian peasants since pre-Columbian times have adapted to Inca, Spanish Colonial, and Peruvian national political changes, as well as accompanying economic changes like the development of commodity markets and neoliberalism.

Michael Kearney takes the opposite perspective, arguing that late-capitalist economic conditions have contributed to the end of the peasant lifestyle. Based on his research in Oaxaca and in California with Zapotec and Mixtec transnational migrants, he contends that, as a classificatory term for contemporary people, the term *peasant* has little utility. He offers evidence that former Mexican peasants are changing into wage-earning laborers who crisscross international borders in search of work. No longer can peasants sustain themselves in this period of late-Capitalism. It has ruptured the basic unit of peasant production—the household, taking former peasants away from agricultural-based subsistence strategies in which they strived for self-sufficiency, and thrusting these people into a global commodity and labor market that can alienate them from their home, community, and cultural traditions. Even when they maintain cultural traditions and stay connected to their communities of origin, the context in which they do so is profoundly altered from when they were peasants.

Marc Edelman, in contrast, does not engage so much in debates about the empirical existence of peasants or the categorical significance or insignificance of peasants. In his research on Costa Rican coffee growers and workers, Edelman observes that his subjects use the term peasant as a type of political identity. It becomes an important way for these growers and workers to politically position themselves against large transnational coffee companies and the government, to oppose international trade agreements and unfair purchasing practices, and to attract the support of non-governmental aid organizations. What is significant is that these growers and workers call themselves peasants.

Although peasant studies do not figure prominently in anthropological research in the early 21st century, peasants and the very concept of “peasant” continue to attract anthropological inquiry and stimulate theoretical debates about classificatory terms, agency, political identity, and even modernity.

— Walter E. Little

PENTECOSTALISM

Pentecostalism is a global religious movement that focuses on the immediate experience and empowerment of the Holy Spirit. It is arguably the most important development in Christianity of the 20th century. Some see it as the third stage in the history of Christianity, from Catholicism to Protestantism to Pentecostalism. It may also be the fastest growing religion in the world today. The anthropological significance of Pentecostalism is that it is global and strongest in Latin America, Asia, and Africa, the traditional locales of most anthropological research. Anthropologists are involved in the flourishing, interdisciplinary field of Pentecostal studies, and have produced several ethnographic case studies.

Origins

According to “Acts 2,” in *The Bible*, the apostles of Jesus gathered in Jerusalem to mark the Jewish holiday of Pentecost, “. . . and they were all filled with

the Holy Spirit, and began to speak with other tongues, as the Spirit gave them utterance.” For centuries, Christians prayed for a New Pentecost, which many believed would herald the return of Christ and the beginning of a millennial kingdom of God on Earth, and there were occasional short-lived movements involving “speaking in tongues” and miraculous “gifts of the Spirit” such as prophecy and healing.

The Pentecostal movement of today is believed to be the product of a synthesis of the principally Methodist Holiness movement of the late 1800s, which was concerned with personal purity and piety, and more ecstatic African American spirituality. It is generally said to have its immediate genesis in two events. First, Charles Fox Parham, a white Holiness preacher, taught that the Holy Spirit could enable a true believer to speak in another language, and several of his students did speak in “tongues,” in the Topeka Revival of 1901. Second, William Seymour, an itinerant African American preacher who had studied with Parham, initiated the Azusa Street Revival of 1906–1909 in Los Angeles. The revival was a sensational event, drawing crowds of people and inspiring ecstatic behavior, particularly speaking in tongues, which became the defining characteristic of Pentecostalism and was understood to be the sign that a convert had experienced a “baptism in the Spirit” as well as a water baptism.

Originally, those who received the “gift of tongues” believed it was a natural language that would enable them to serve as missionaries to other peoples. In addition, they saw it as a sign of the imminent return of Christ, lending urgency to their missions. Almost immediately, converts fanned out across the world, establishing Pentecostal missions in approximately fifty countries in the first 2 years. They quickly, and of course disappointingly, discovered they could not actually speak other natural languages, although that did not prevent them from spreading a new Christianity, founded on an ecstatic engagement with the Holy Spirit, to the sick, the weak, the poor, and the disenfranchised in particular. Today, Pentecostals understand “tongues” as a “heavenly language,” not a natural one.

Growth

The Azusa Street Revival collapsed in 1909, as principal figures quarreled and separated, generating the first of a rapidly and endlessly proliferating number

of Pentecostal churches, movements, sects, and denominations. Pentecostalism grew exponentially throughout the 20th century, tripling in adherents from 1970 to 1990. Today, estimates of the number of Pentecostals in the world range from 250 to 523 million people, accounting for at least 1 in 8, and possibly 1 in 4, Christians, and at least 1 in 25 people in the world. It is predicted that Pentecostals will outnumber Catholics and become the main form of Christianity in the 21st century. As two of three Pentecostals live in the nonwestern world, and over 70% are nonwhite, the rise of Pentecostalism is changing the global face of Christianity. Latin America has the largest number of Pentecostals, followed closely by Asia and Africa, then North America; Europe has by far the lowest number. Catholic Brazil has the largest number of Pentecostals of any country in the world.

Types

Pentecostalism is often confused with two related movements, Fundamentalist Christianity and Evangelical Christianity. Fundamentalists believe in the inerrancy of scripture and reject the idea of supernatural gifts or charismata in this day and age, and Evangelicals believe that salvation requires a conversion experience of spiritual rebirth. Pentecostalism goes beyond them in emphasizing charismata or spiritual gifts, particularly speaking in tongues, as signs of conversion and it relies on divine inspiration and guidance in addition to scripture.

There are thousands of Pentecostal denominations. All scholars recognize two “waves.” First, Classical Pentecostalism refers to 660 denominations that developed in the West from the Azusa Street Revival. Second, Charismatic Pentecostalism refers to a Pentecostal movement in the mainline Protestant and Catholic churches, beginning in the 1960s. Some scholars refer to a “third wave” of newer, independent, Pentecostal-like churches that place less emphasis on tongues and generally do not call themselves Pentecostal or Charismatic. Some focus on “spiritual warfare,” believing that demonic spirits control the world. Others promote a “health and wealth” or “prosperity gospel.” Some scholars also include the huge number of independent, indigenous, Pentecostal-like churches of Africa and Asia in this third wave, creating a “catch-all” category called Neo-charismatics, the largest of the three types.

Theology

Pentecostalism focuses on religious experience and praxis rather than belief and doctrine. Pentecostals follow the “fourfold” or “four square” gospel of Christ as Savior, Sanctifier or Spirit-Baptizer, Healer, and Soon-coming King. They believe that a Christian is a person who has experienced salvation from sin and eternal damnation through a conversion experience that culminates in a baptism in the Spirit. The convert is a changed person, developing a personal relationship with Jesus and rejecting the satanic world of sin and suffering. Speaking in tongues is a sign of salvation, which often also leads to other “gifts of the Spirit” such as healing and prophecy. Pentecostals look to the Holy Spirit for divine guidance and assistance in their lives. They believe that problems may be due to demons, and rely on faith, prayer, and sometimes exorcism for deliverance from evil. Pentecostals are formidable proselytizers and take great pride in church growth. They also hold an apocalyptic, pre-millennial eschatology, believing in the imminent Second Coming of Christ when a godly kingdom called the Millennium will be established.

Sociology and Anthropology

The Azusa Street converts were largely poor, uneducated laborers who did not feel welcome in mainstream Christianity. Likewise, the movement has typically appealed principally to marginalized and displaced persons around the world, particularly migrants to rapidly growing cities. Classical Pentecostalism in the United States, however, gradually became middle class and is moving closer to Fundamentalist and Evangelical Christianity. Adherents in the Third World are still overwhelmingly poor and working class, but middle class support is growing there too.

Social scientists have been trying to explain the incredible growth and appeal of Pentecostalism, and the functions it serves. One simple factor is that Pentecostal services are typically exciting, energetic, cathartic, entertaining events. Pentecostals make very effective use of music and technology, and services in the larger congregations are often elaborate staged performances. Pentecostals are also incredibly effective at “harvesting” new souls for the church. Every member is expected to bring more to the fold. Each new convert is hailed as a victory for Christ. This

aggressive evangelism, some have suggested, is a good training ground for the world of business.

Pentecostals are also said to have an organizational genius. It is generally a decentralized religion. Congregations typically enjoy much autonomy but also participate in an extensive network of voluntary fellowship with other congregations. Pentecostals around the world are increasingly linked by a transnational network of electronic communications, publications, missions, crusades, and globetrotting evangelists, drawing adherents everywhere into the globalization process. Pentecostal congregations enjoy a high degree of lay participation and control, which may promote democratic attitudes. The idea of the priesthood of all believers—that every Christian is capable of inspiration and has the right to interpret scripture—encourages an egalitarian attitude. Leadership, even at the national level, is usually indigenous rather than under the direction of foreign missionaries. Women are particularly prominent in the movement and may be attracted by the opportunities it offers for leadership and power.

Many scholars see Pentecostalism as a response to material and social deprivation and anomie. They argue that the movement helps adherents cope with radical changes generally associated with modernization or globalization, including rural-to-urban migration, the growth of mega-cities, bureaucratization, the expansion of capitalism, and urban poverty. The Pentecostal congregation is typically close-knit and very supportive, helping its members respond to daily needs and crises. The importance of healing, in the broad sense of solving individual problems, seems to be a major attraction for the poor. The strict discipline of Pentecostal morality produces sober, hard-working, honest, trustworthy, and dependable employees. Pentecostalism also seems to promote stronger and more stable marriages and families.

One of the most interesting facets of Pentecostalism, for the anthropologist, is that it adapts easily to any culture, absorbing much of the culture while at the same time demonizing indigenous religions. It is paradoxically both global and local. The Pentecostal movement is clearly a force to be reckoned with in the 21st century. It began as an otherworldly religion and has been largely apolitical, but there are signs of increasing politicization, which can only increase its influence on the local and worldwide scene.

— William Wedenoja

PEOPLE'S REPUBLIC OF CHINA AND TAIWAN

Any consideration of cultural diversity in the world, past and present, cannot ignore the People's Republic of China and Taiwan. The modern political units in this part of East Asia changed significantly during the 20th century. In 1949 Mao Zedong (Mao Tse-tung) established the People's Republic of China (PRC) on the Chinese mainland after defeating the Nationalist Party or Guomindang (Kuomintang) troops led by Jiang Jieshi (Chiang Kaishek). At that time, Jiang established the Republic of China in the islands that constitute Taiwan. In 1997 Great Britain returned the islands in the territory of Hong Kong to the PRC, and in 1999, Portugal returned the territory of Macau to the PRC. Although publications tend to treat Chinese culture throughout these modern political units as homogeneous, there is significant regional variation in language, subsistence practices, housing, crafts, social organization, and ritual life. In addition there are numerous officially recognized ethnic groups living in these regions of East Asia. There is no doubt that such regional cultural variation first developed during the prehistoric period.

In addition, the total area cannot be ignored by virtue of its large size and huge population. At present the PRC has the largest population on earth, with over 1 billion people. There also is great physical

diversity. The PRC is somewhat larger in size than the United States, with climatic zones spanning from cold temperate in the north to subtropical in the south. In the south, the favorable climate and beaches have made Hainan island a major tourist destination. Historically, northern China is often referred to as including those areas north of the Yangzi River (or Yangtze, also known as Chang Jiang). The largest river in northern China is the Yellow River (Huang He). Another major river in southern China is the Zhu (Pearl) River. Western and southwestern areas of the PRC are mountainous, while there are many fertile plains in the central and eastern portions. The Himalayan mountains, which include portions of Tibet, are the highest on earth. The striking limestone mountainous areas of the southwestern Chinese mainland are known for their beauty. There are several famous mountains in the PRC that were revered throughout history and in modern times by poets, painters, devout Buddhists and Daoists (Taoists), and lovers of nature.

The mountainous islands of Taiwan lie in a subtropical zone. Early European explorers named these lush, beautiful islands Formosa, but the name is no longer used. Taibei (Taipei), situated in the north area of the main island, is densely populated. The east coast of the main island is known for its stunning views of the ocean. Typhoons, or large tropical storms, are common during the summer months in Taiwan and on the southern Chinese mainland.

The time depth of human cultures in this large area of East Asia is of a scope that is rarely matched in other parts of the globe, including the Pleistocene period, later prehistoric periods with Neolithic cultures, up to a long historic period (including several dynasties). There is evidence for numerous turning points in human development, such as the

The People's Republic of China and Taiwan

transition to physically modern humans, the establishment of farming, the development of urbanism, the rise of early states, the invention of bronze metallurgy, and the invention of writing. Archaeological research, involving the study of material remains, is complemented by interpretation of rich and diverse early historical texts from the area. Many writers have noted that Chinese civilization is one of the oldest and most enduring civilizations in the world. Some cultural practices that developed early have continued to the present day, such as belief in the importance of ancestors and rituals involving food offerings.

During the 20th century, and through the onset of the 21st, there has been significant cultural change in China, especially in relation to economic development. For example, explosive economic development during the past two decades in the PRC has integrated formerly isolated areas with others and attracted labor from rural to urban settings. Differences in wealth between individuals have increased dramatically. Some traditional life-ways in rural areas are being abandoned in favor of urban customs. For example, traditional craft production (textiles,

The Huang Shan mountains, Anhui province

pottery, wooden implements) is declining. As economic development and cultural change takes place, however, people in the PRC and Taiwan remain justifiably proud of their rich cultural heritage.

Historic and Modern Cultural Diversity in the PRC and Taiwan

In the PRC, there are 56 officially recognized ethnic groups (*minzu*). The largest of these is called the Han. The 55 ethnic minorities are often referred to as “nationalities,” emphasizing their different histories

from that of the Han people. Ethnic identity here, as elsewhere, however, is a complex and changing phenomenon. Many ethnic minority peoples live in western and southwestern China, including areas bordering other modern countries. Modern political borders make it difficult to realize that peoples with similar cultural traditions live in neighboring countries of southeast Asia and other areas. Several provinces in the PRC have autonomous zones where one or more ethnic minority groups of people are concentrated. Ethnologists who specialize in ethnic minority cultures and languages tend to work at research institutes for that purpose, rather than in departments of anthropology.

In Taiwan there are several historically known aboriginal peoples who lived in the islands before the major migration of mainlanders in the first half of the 20th century. Most historical accounts identify nine ethnic groups, and today they comprise a small percentage of the population. Many aboriginal peoples adopted urban lifestyles at relatively early dates, given the rapid industrialization process in Taiwan. These indigenous peoples of Taiwan all once spoke languages belonging to the large Austronesian language family. There are linguistic similarities over a broad region, from tropical Asia to the Pacific islands. In Taiwan many professionals who research ethnic minority cultures regard themselves as anthropologists. A department of anthropology was established at a relatively early date at Taiwan National University in Taipei. It

should be noted that there also were historically significant earlier migrations of Han mainlanders to Taiwan, especially during the 17th century. Many migrants came from Fujian province, directly across the Taiwan Straits.

In addition to cultural diversity in the area that comprises the PRC and Taiwan, there is tremendous linguistic diversity. For example, the official language in the PRC is Mandarin Chinese. Children from all ethnic backgrounds throughout the country learn the same Chinese characters. For many characters there are both simplified and complicated forms. In an

effort to increase the literacy rate after 1949, the government of the PRC simplified many Chinese characters (an act that later generations of foreign students were grateful for). In Taiwan, however, people use the more complicated traditional characters. Throughout the PRC there is marked variation in spoken Chinese. There are several distinct dialects that generally vary by geographic area. The most marked is the difference between Mandarin Chinese and Cantonese, spoken by people in southernmost China, especially Hong Kong. Most northerners cannot understand Cantonese at all. Cantonese is the dominant form of spoken Chinese in many China towns in North America, since adventurous, early immigrants came primarily from southern, coastal areas. Within one single province, also, there can be several regional dialects. Many individuals have the ability to converse in their own dialect, or the national common dialect (referred to as *putong hua*), depending on the context.

Learning the Chinese language is a challenge for everyone. Educated people tend to recognize up to 5,000 characters. In addition, Chinese is a tonal language. Students must learn the proper tone (one of four) for a given sound in order to convey the proper meaning. In an effort to help foreign business people, tourists, and students know how to recognize and pronounce key words, the government of the PRC is providing increasingly more signs with the romanization of Chinese characters. The first romanization system widely used in North America is called Wade-Giles, and this system continues to be used in Taiwan. The PRC adopted the pinyin system of romanization. The difference can be seen in the spellings for the capital of the PRC, once referred to as Peking, and now more commonly referred to as Beijing.

In many areas of the PRC where ethnic minority peoples live, children learn standard Chinese as well as their own languages. For example, in the northwestern province of Xinjiang, many children of the Uighur (or Uyghur) minority group speak and write the Uighur language, a Turkic language. The

Temple of Heaven (Ming Dynasty, 1368-1644), Beijing

Source: Photograph courtesy of Anne P. Underhill.

Naxi people of Yunnan province had their own traditional written language using pictographs. Another distinct language within the PRC is Tibetan, spoken not only by people within Tibet but also in communities in neighboring areas. The Manchu language became more widely used during the Qing (Ching) dynasty (1644 to 1911 A.D.), when the emperors came from the Manchu ethnic group of northeast China.

In these areas of East Asia there is substantial regional variation in subsistence practices, housing, social organization, and ritual life. Subsistence

systems in the eastern areas of the northern Chinese mainland were historically based on millet agriculture. Later rice became the preferred grain, and it has been grown in some relatively warm areas of northern China such as southern Shandong province. Relatively recent staple foods in northern China based on wheat and other grains include several varieties of noodles and steamed breads. A characteristic of the Central Plain (particularly in Henan province) and adjacent areas in the lower and middle Yellow River valley is loess, a type of fine, silty soil. In upland areas of the middle Yellow River valley, deposits of loess can be several meters thick. In parts of modern Shaanxi province, for example, cave homes are carved out of the deposits. For countless generations, farmers in several areas of the Yellow River valley have had to cope with extensive flooding caused by the extensive silt deposits.

Some inhabitants of northern and western areas of the Chinese mainland have had nomadic lifestyles. People of the Kazak ethnic group in Xinjiang have traditionally lived in yurts, moving seasonally to care for herds, commonly sheep and cows. Similarly, in Tibet, people have moved with the seasons to care for herds of animals such as sheep and yaks. They rely extensively on yaks for transporting goods as well as meat, milk and butter. There are also some Tibetan

communities of settled agriculturalists. Arable land here is scarce, and barley is the main crop. Uighur farming families living in lowland areas of Xinjiang are also known for their beautiful embroidered and other colorful textiles.

In lowland areas of the south, paddy rice has been the dominant crop. The labor-intensive method of transplanting seems to have been in use since the Han dynasty, roughly two thousand years ago. House styles and craft production are adapted to the warmer, more aquatic environments of the area. Many varieties of bamboo are

found here and are used for a variety of household items, as well as food. Fishing and travel by boat, on rivers as well as the sea, are important activities. Water buffalo are commonly used as draft animals in farming. In the southernmost, subtropical areas, there are several varieties of domesticated and wild plants that cannot grow in the north. In Taiwan, for example, the root crop taro is grown, and tropical fruits thrive such as mango and star fruit.

Two southerly areas of the PRC with exceptional cultural diversity are Yunnan and Guizhou provinces. Although ethnic minority peoples in these provinces tend to share similar customs with their Han neighbors with respect to subsistence practices and housing, there are marked differences in traditional clothing. A physical symbol of one's social identity in many areas is the nature of textiles worn (materials, styles, designs), as well as ornaments. For instance the Miao people in Yunnan and Guizhou are known for the stunning silver headdresses and ornaments that women traditionally wear during festivals.

Similarly, several ethnic minority groups in Taiwan, such as the Ami in the scenic east coast area, have equally beautiful traditional textiles and ornaments. In addition the Yami people of Lan Yu (Orchid Island; once known as Botel Tobago) are famous for their brightly painted boats. These people enjoy chewing

Yami fishing boats, Orchid Island (Lan Yu), Taiwan

Source: Photograph courtesy of Anne P. Underhill.

betel nut, a mild stimulant also popular in the Pacific region. Traditional Yami houses of wood are raised on wooden posts. In more than one southerly area traditional customs are being retained, in part for a growing tourism industry. Several museums are devoted to showcasing the rich ethnic minority cultures in many regions of the Chinese mainland and Taiwan.

There also has been considerable regional diversity with regard to social organization and ritual life. These aspects of culture do not neatly correspond with ethnic identity. Significant characteristics of historic and modern Han culture, and some ethnic minority cultures, in both northern and southern areas include the importance of extended family relations and tracing lineal descent through male ancestors. Traditional Confucian values that remain include respect for elders and authority figures. Confucius (551–479 B.C.) and his students also believed in the superiority of men over women, but attitudes about this issue have changed greatly

since then. For many years, for example, women have run their own businesses, have had important positions in government, and have conducted important scientific research. Similarly, during the Warring States period (481–221 B.C.), an era of social upheaval and change, Daoist (Taoist) and other philosophers contemplated the social roles and responsibilities of individuals. There are Daoist temples on the Chinese mainland, Hong Kong, and Taiwan from several eras devoted to various deities and immortals.

Many rituals among the Han and some ethnic minority groups are associated with ancestral veneration. During certain times of the year, which vary by region, families burn incense in honor of the deceased and place offerings of food and drink by graves. For the Han Chinese, white is the traditional color of clothing worn as a sign of mourning during funerals. Paper items such as symbolic money may be burnt as offerings for the deceased to use in the next world. In southern areas, temples have been

particularly important loci of periodic rituals for lineage members.

Another form of ritual practice that seems to have a long antiquity in the Chinese mainland and insular areas is shamanism. There are practicing female shamans among the Puyuma of Taiwan, who aim to address spirits in order to cure people. Such research specialists have been known in other parts of East Asia as well, such as Korea.

Buddhism was first introduced to the Chinese mainland sometime during the Han dynasty (206 B.C.–220 A.D.). The Han empire was of a scale comparable to the Roman empire. The Han state expanded to westerly regions for purposes of trade and defense. Over time, Buddhism was embraced by emperors and ordinary people alike. Buddhist temples and pagodas from several historical eras are common in the PRC and Taiwan. In the PRC, there are several stunning cave temples, some built on a massive scale. In the Chinese mainland, Hong Kong, and Taiwan, there also are many temples devoted to local Buddhist deities. Patrons may engage in certain rituals to seek information about their futures.

Diverse forms of social organization and ritual life are historically known among many ethnic minority peoples in both northerly and southerly areas. In traditional Tibetan societies for example, a practical adaptation in the past to the challenging natural environment (with limited agricultural land and the need for animal husbandry as well) was fraternal polyandry (brothers sharing a wife). Buddhism is the traditional religion of Tibet.

Northern areas of the PRC in particular also contain significant populations of Hui, or Muslim people. Islam was introduced to China during the Tang dynasty (618–907 A.D.). Some of these people choose to wear distinctive headgear, while the beliefs of others can mainly be recognized by their avoidance of pork. Several cities throughout the PRC have active mosques. They are especially common in Xinjiang province, in areas where Uighur, Kazak, and other peoples live.

In the southwestern Chinese mainland there is great diversity in social organization and ritual life. Here, some ethnic minority groups have been known that are traditionally matrilineal, meaning that descent is traced through females. Women are the managers of these household economies, and the institution of marriage, as known among the Han people, does not exist.

During the 19th century, Christian missionaries from North America and Europe traveled throughout the Chinese mainland, Hong Kong, and Taiwan. Some ethnic minority and Han peoples have continued to practice Christianity since then, and there are active churches in a number of areas.

Archaeology in the PRC and Taiwan

The field of archaeology is well developed in the PRC and Taiwan. There are numerous professional archaeologists conducting both rescue and research excavations in every region as well as graduate programs for training future generations of archaeologists. The practice of archaeology has deep personal meaning for these professionals, since there is great pride in uncovering evidence for the development of Chinese civilization. To many professionals, archaeology is a means of tracing evidence about one's personal ancestors. At many universities in the PRC, archaeology is taught in departments of history. In Taiwan, many professionals regard archaeology as a subset of the field of anthropology. In both the PRC and Taiwan there are research institutes for archaeology as well. Archaeologists in all areas share common goals of using material remains to research issues such as change in technology, subsistence practices, social organization, and ritual life. Many also employ the rich and diverse texts from various eras of Chinese history to inform them about life in the past. There are numerous professional journals at the regional and national levels. Professional archaeologists devote considerable time to sharing their findings with the public, by writing books for the public and conducting interviews for television shows and newspaper articles. Archaeology is a priority for government officials; considerable funding is devoted to the construction and maintenance of new museums at the local, regional, and national levels.

Residents of the Chinese mainland and foreigners alike have long been fascinated with Chinese antiquity. At least as early as the Han dynasty (206 B.C.–220 A.D.), scholars recorded information about the past. During the Song dynasty (960–1279 A.D.), scholars wrote catalogues describing ancient bronze ritual vessels. In the late 1800s and early 1900s, European travelers conveyed information to their fellow citizens about fascinating ancient sites that they had seen. Certain individuals, such as Aurel Stein,

from Britain discovered key sites and inspired sinologists to conduct important research on historical texts and other materials. An established method for collecting and interpreting data about life in the past, including the crucial context of objects, not just the objects themselves, began to develop after the establishment of the field of geology in China. The creation of the Geological Survey of China was a turning point, and it also fostered an atmosphere of scientific collaboration among Chinese and foreign specialists.

Soon a series of excavations took place, revealing a number of important ancient cultures. The first excavation in 1921 was directed by the Swedish geologist-turned-archaeologist Johan Gunnar Andersson, with an international team, at a Neolithic (farming subsistence base) site called Yangshao in Henan province. Scholars later determined that the Yangshao culture spanned from ca. 5000–2800 B.C., with a wide distribution area in the middle Yellow River valley. Another extremely important series of early excavations took place at the late Shang period (ca. 1200–1046 B.C.) site of Anyang in northern Henan. Li Ji (Li Chi) directed a team of professional Chinese archaeologists that recovered not only important remains from the early Bronze Age capital site, but also large quantities of oracle bones, the earliest known writing in China. Subsequent teams of archaeologists discovered evidence for a late

Neolithic culture in Shandong province called Longshan (ca. 2600–2000 B.C.), on the basis of excavations at Chengziyai from 1930–1931 and at Liangchengzhen in 1936.

Shortly before the PRC was founded in 1949, Li Ji (Li Chi) and some other archaeologists went to Taiwan and established the field of archaeology there. Some of the excavated remains from Anyang and

Neolithic sites were moved to Taiwan. These scholars trained a new generation for archaeological research. Research in Taiwan has continued to focus on mainland sites as well as key sites in Taiwan. Meanwhile, the new government on the mainland began to establish research institutes for archaeology, departments within universities, museums, and professional journals.

Previously, Marxism was the dominant theoretical approach to interpreting archaeological remains in the PRC. For the last two decades especially, archaeologists have employed a variety of theoretical and methodological approaches. Since the early 1990s, the government of the PRC has allowed collaborative fieldwork projects with foreign archaeologists. These projects have included several systematic, regional survey projects and excavations at Paleolithic, Neolithic, and early Bronze Age sites. Chinese archaeologists have worked with numerous other professionals from Japan, Korea, Europe, Australia, Canada, the United States, and other areas. Archaeological fieldwork is taking place in every province of the PRC, and increasing numbers of local people from diverse backgrounds are participating. In addition there are Bureaus for the Management of Cultural Relics at the local, provincial, and national levels to monitor the research and protect sites.

The archaeologist who introduced ancient China to English speakers in North America and elsewhere is Zhang Guangzhi (Chang Kwang-Chih), known as K.C. Chang. Chang was widely admired by archaeologists in the PRC, Taiwan, and the West. His monumental syntheses and innovative, anthropological interpretations about the rise of civilization in ancient China, as well as description of his archaeological methods will remain as required reading for everyone. His voluminous articles and books, in both Chinese and English, span a period from 1953 to 1999.

Findings From the Paleolithic, Neolithic, and Early Bronze Age Periods

After the initial focus of archaeological fieldwork in the northern Chinese mainland, excavations and surveys have taken place in every region of the PRC and Taiwan. The extensive fieldwork and publications demonstrate that investigating the

rise of Chinese civilization requires consideration of the diverse cultures from many areas. Also, archaeologists who wish to consider cross-cultural evidence for different kinds of social change in the past cannot ignore the rich data from the PRC and Taiwan.

Hundreds of Paleolithic sites have been discovered in several regions. These sites are providing information about topics such as the physical development of modern humans, adaptations to different kinds of environments during the Pleistocene period, and regional variation in stone tool technology. There are many challenges in interpreting sites on the Chinese mainland attributed to the Early Pleistocene period, over ca. 700,000 B.P. (before present, or years ago). There have been controversies about dating of remains, integrity of the stratigraphic deposits (i.e., whether there has been disturbance), and identification of artifacts (versus objects formed by natural processes). Currently it appears that some of the earliest stages in the physical and cultural development of hominids took place on the Chinese mainland in addition to Africa. A handful of sites appear to have dates older than 1 million years ago, including more than one locality in the Nihewan Basin in northwestern Hebei province.

In contrast there are numerous sites from the Middle Pleistocene period on the Chinese mainland. The most famous is Zhoukoudian (Chou-k'ou-tien), near Beijing, discovered in 1922 by Johan Andersson, with the main deposits dating ca. 500,000 B.P. Subsequent excavations by Pei Wenzhong and others yielded abundant remains of *Homo erectus* that were referred to as "Peking Man." Tragically, these remains were lost during World War II. Important new research continues to take place at the site, where caves yielding skeletal remains, remains of animals such as hyenas and saber-toothed tigers, and stone tools indicative of a Lower Paleolithic technology have been found. Zhoukoudian is one of the richest Paleolithic sites in the world, with evidence for over 200,000 years of occupation. The key institution conducting excavations at Paleolithic sites in the PRC is called the Institute of Vertebrate Paleontology and Physical Anthropology (IVPP). Other comparable sites yielding *Homo erectus* remains and/or stone tools exhibiting a Lower Paleolithic technology have been found in Shaanxi, Shanxi, Liaoning, Guizhou, Yunnan, and other provinces. It is clear that *Homo*

erectus populations were able to adapt to a wide variety of environmental regions in both northern and southern China.

Late Pleistocene sites, both open air and cave sites, have been found in an equally wide area. These include sites (ca. 200,000–40,000 B.P.) with early *Homo sapiens*' skeletal remains and stone tools exhibiting a Middle Paleolithic technology. One key site where archaic *Homo sapiens* remains and stone tools were recovered is Dingcun in southern Shanxi. Later sites, after ca. 40,000 B.P., have remains of fully modern humans (*Homo sapiens*) and an Upper Paleolithic stone tool technology.

A clear trend evident from sites on the Chinese mainland, as elsewhere, is diversification of stone tool technology. There was increasingly more specialization of tool forms and more efficient use of stone. Microlithic tools have been found in several sites. Sites such as Xiachuan in southwestern Shanxi yielded a variety of blades, scrapers, and points. Current research focuses on delineating regional variation in subsistence practices (hunting, gathering, shelter) and tool technology. The Upper Cave at Zhoukoudian (ca. 15,000 B.P.) is important for what may be the earliest evidence for mortuary rites in China. It appears that mourners spread hematite over the bodies. Archaeologists also found a variety of bone and antler tools at Late Pleistocene sites, and ornamental items of both stone and bone. The Changpin (Ch'ang-pin) site on the east coast of Taiwan probably dates to ca. 15,000–20,000 B.P. Preliminary scientific analyses indicate that the earliest human remains here date to ca. 20,000 B.P.

Numerous prehistoric cultures from the Holocene period after ca. 7000 B.C. have been identified all over the Chinese mainland and Taiwan. There is evidence for diversity in regional cultural traditions, but unity as well. Research shows that northern China was a locus of early millet cultivation. Sites from the Peilgang culture such as Cishan in southern Hebei yielded domesticated millet ca. 6200–5000 B.C. More research has taken place in the south, where early sites with wet rice cultivation have been found in the central and lower Yangzi river valley. At Pengtoushan culture sites, ca. 7000–5200 B.C., such as Bashidang in Hunan, large quantities of rice and pile dwellings were discovered.

Later Neolithic cultures based on farming (ca. 5500–4000 B.C.) become more diversified, with more distinct traditions of subsistence practices, craft

production, and mortuary practices. Some Yangshao sites, such as Jiangzhai in Shaanxi, reveal community planning and more than one house style. In the Yellow River valley at this time, multiple burials were more common. Waterlogged deposits at the Hemudu site in the lower Yangzi river valley revealed a wide variety of craft goods, including a lacquer container, a boat oar, reed mats, finely incised bone artifacts, and bone whistles. Meanwhile, people in subtropical Taiwan from the Dapenkeng (Ta-p'en-k'eng) culture, after ca. 5000 B.C., may have grown taro like their descendants.

Significant social changes took place during the late Neolithic period in more than one area of the Chinese mainland and Taiwan. Differentiation in housing and burials indicate that social ranking emerged during the period ca. 4000–2600 B.C. Greater quantities of prestige goods, such as jade items and labor-intensive pottery vessels, were produced. On a regional scale, archaeological surveys reveal the emergence of settlement hierarchies. Public rituals occurred on several large sites, most notably at the Hongshan culture site of Niuheliang in western Liaoning province. A minority of large, rich graves is a characteristic of several sites, such as Dawenkou (Dawenkou culture, Shandong province) and Fuquanshan (Liangzhu culture, near Shanghai).

Travel by boat must have been common on the open seas in addition to rivers and lakes. The Penghu (P'eng-hu) islands between Taiwan and Fujian were first occupied as early as ca. 3000–2500 B.C. On the southeast mainland and on Taiwan, successful ways of life continued for hundreds of years; there were similar late Neolithic cultures, ca. 2000 B.C. and later. Another important Neolithic culture of Taiwan is the Fengbitou (Feng-p'i-t'ou) culture, dating ca. 1500–500 B.C. The Beinan (Peinan) slate burials of the east coast (ca. 2500–800 B.C.) have fine jade ornaments and dental evidence for chewing betel nuts, like later peoples in southern Taiwan.

In several areas of the Yellow River and Yangzi River valleys, regional systems of social organization became larger and more structurally complex during the Longshan period (ca. 2600–1900 B.C.). Large settlements, some surrounded by earthen walls, appear to have been regional centers. This pattern, coupled with increased nucleation of regional populations, indicates the beginnings of the process of

The Great Wall

urbanization. Key sites from this period include Taosi, Wangchenggang, Liangchengzhen, and Shijiahe. Even more labor-intensive forms of prestige goods were produced, and relatively few people had access to them. The most striking example is the famous

hundreds of prestige goods (especially bronze vessels and jades). The most notable is the tomb of Fu Hao, the consort of a late Shang king, known from the oracle bone inscriptions as a military leader in her own right. During the late Shang period, ritual duties,

“eggshell” black pottery stemmed cups, literally the thickness of an eggshell. More research on the economic bases of these regional polities should provide evidence for loci of production and inter-community exchange of goods, as well as the nature of leadership.

The earliest known state period represented at the Erlitou site in west-central Henan dates to ca. 1800–1600 B.C. During the Erlitou period, metallurgy was mastered. At this time elites preferred to bury bronze drinking and eating vessels with the deceased, rather than fine ceramic wares as previously. During later phases of the early Bronze Age, a number of states developed. The early Shang state became powerful ca. 1600 B.C., and the state expanded over time, with major centers at Yanshi and Zhengzhou in west-central Henan, Daxinzhuang in western Shandong, and the late Shang site of Anyang after ca. 1200 B.C. in northern Henan.

The presence of powerful rulers at these Erlitou and Shang period sites is clear, from abundant skeletal evidence for human sacrifice, bronze weapons, foundations of large palaces, and graves containing

such as making sacrifices of humans and animals to powerful ancestors, formed a key component of leadership.

Meanwhile, powerful states had emerged in other parts of the Chinese mainland. At Sanxingdui in Sichuan, archaeologists were stunned to find evidence of an independent, and very different, tradition of metallurgy. They excavated ritual pits containing huge bronze heads and entire figures, along with numerous elephant ivory tusks. Archaeologists also found a walled settlement area, indicating a regional center of a state contemporary with the earlier Shang period in Henan province.

The late Shang oracle bone records indicate that warfare was a major concern of kings. Eventually the Shang state was conquered by peoples from further west in the Yellow River valley, establishing the Western Zhou dynasty. The Western Zhou state (1046–771 B.C.) controlled a wide area of the Yellow River valley by means of strong local administrative units. Several Western Zhou sites have been found in southern Shaanxi. Many of the ritual elements of kingship were continued from the Shang, such as burying large quantities of goods with deceased elites who were about to become powerful ancestors. There also is abundant archaeological evidence for smaller, independent states during the Western Zhou period, such as the Yan state located near Beijing.

Eventually, the large Western Zhou state centered in Shaanxi began to disintegrate. During the subsequent Eastern Zhou period (including the Spring and Autumn and Warring States phases, 771–221 B.C.), different states in both north and south China vied for power. Warfare increased in intensity and scale as well as frequency. The period also is known for its technological innovation (including the more widespread use of iron), as different states competed to produce new forms of weapons and prestige goods. During these later phases of the early Bronze Age, increasingly diverse forms of written records were employed. Philosophers and teachers, such as Confucius from the state of Lu in modern Qufu, contemplated the tumultuous era in which they lived, advocating virtuous behavior and social harmony. Contemporary sites from the Chu state in Hubei and Hunan provinces have yielded exquisite wooden and lacquer artifacts.

Meanwhile, an independent Bronze Age culture emerged in Yunnan province. The earliest phases

of the Dian culture in western Yunnan developed during the 11th century B.C., and spread to central Yunnan during later phases until the 1st century A.D.

Eventually in 221 B.C., the Qin state conquered all the other warring states, and China's first empire was born. The emperor Qin Shihuangdi attempted to maintain his power by beginning the construction of the Great Wall. Later generations of rulers would order the construction of new sections of the wall. The empire did not last long, as the emperor died in 206 B.C. Parts of his astonishing mausoleum near Xian city have been excavated, yielding the famous pits where hundreds of life-sized terracotta soldiers were discovered—evidently modeled after real people who served the emperor. The location of his tomb is known but remains unexcavated.

For consistency, this essay first cites Chinese names using the pinyin romanization system established in the PRC. In parentheses it provides some equivalent words using the Wade-Giles romanization system that was formerly more common in North America and that has been used in Taiwan. It presents surnames first (such as “Mao”), the convention in both the PRC and Taiwan. References at the end of this essay are listed according to the North American system.

ASIA

On Sunday, December 26, 2004, in the wake of an earthquake in the Indian Ocean ranking 9.0 on the Richter scale, immense tidal waves known as *tsunami* ravaged large sections of Asia and a small area of Africa with little or no prior warning, destroying whole areas and devastating populations. Countries most directly affected by the tidal waves included Indonesia, Thailand, India, Malaysia, the Maldives, Sri Lanka, and Myanmar in Asia and Somalia in Africa. Tourists and visitors from around the globe also lost their lives when the tsunamis swamped beaches, hotels, and tourist attractions in the affected areas. Almost 300,000 people were reportedly killed by the tsunamis, and another 3 million suffered from the destruction of their families, their health, and their livelihoods. A number of individuals and businesses that survived the direct attack by the tsunamis were severely affected by its aftermath. Studying the implications of the tsunamis of 2004 will occupy anthropologists and other scholars for decades.

One of the most interesting anthropological aspects of the 2004 tsunamis will be the examination of the impact of globalization on relief efforts as nations, groups, and individuals around the world complied with the call to help raise the \$10 billion needed for relief efforts, as estimated by the United Nations. By March 2005, the United States had committed \$350 million to tsunami relief, with plans for an additional \$6 million to supplement the initial commitment. The European Commission announced that it had created a reconstruction package for Asia valued at 350 million euro, with 100 million euro targeted for relief in Sri Lanka. New Zealand directed the

equivalent of \$1.08 million for relief and restoration toward the Maldives. China pledged the equivalent of \$153.4 million.

While it might be expected that foreign governments and international aid agencies like the International Red Cross and the United Nations would rise to the call for financial and physical assistance, responses from developing nations, individuals, and groups large and small have also demonstrated the strength of globalization in the 21st century. For instance, Nigerians held a fundraiser for tsunami victims on March 3, 2005, with a goal of raising \$20 million. Representatives at the Sri Lankan embassy in China sold jewels to raise money for children orphaned by the tsunamis. In the Netherlands, a group of organizations contributed the equivalent of \$240 million to Asian tsunami relief. In the Canadian city of Vancouver, members of a Buddhist congregation planned to sell their temple to raise \$1 million for tsunami relief.

Those who assisted tsunami victims spanned all nationalities, races, ethnicities, ages, social classes, and religions. Churches of all faiths donated to tsunami victims without asking the faith of those who would receive assistance. Celebrities around the world staged benefits, and schoolchildren sold lemonade, held bake sales, and broke open piggy banks to assist in tsunami relief. Teams of doctors, nurses, and other trained personnel traveled to the area to assist survivors, while teams of volunteers worked tirelessly to identify remains of those who did not survive.

In addition to the body of research that cultural anthropologists are expected to contribute on issues arising from the 2004 tsunamis, archaeologists are involved in examination and analysis of new discoveries uncovered by tsunami waves. For instance, the Archaeological Survey of India undertook efforts to locate ancient temples after residents observed these relics before they were again covered by water. Archaeologists subsequently discovered an ancient temple on the southern coast of India that is thought to be part of Mahabalipuram, a mythical Hindu city. Other relics have also been discovered on the coast of Tamil Nadu. The tsunami discoveries were presented at an international seminar on maritime archaeology in March 2005, in New Delhi, India.

— Elizabeth Purdy

GREAT WALL OF CHINA

The Great Wall of China has been described as being like a giant dragon snaking its way across northern China. From east to west it runs across mountains, valleys, and bodies of water for approximately 4,163 miles (6,700 kilometers). Although there are roads that are longer, the Great Wall is the longest structure ever built by humans. It is visible to astronauts from earth orbit.

The Great Wall starts on China's east coast at Shanhaiguan, which is a town near the city of Qinhuangdao. It ends in western China close to the town of Jiayugun. It was built to defend China from invasions by tribes from Mongolia and Siberia.

Anthropologists include the Great Wall in the study of ancient cultures, or prehistorical human life, because the date and place for the beginning of its construction are unknown. Probably, it was begun at least 2,400 years ago during the Spring, Autumn, or Warring States periods of Chinese history. Successive dynasties built, expanded, or ignored it until around 400 years ago.

At first, parts of the Great Wall were built in different Chinese states. After northern China was unified, parts of the wall were tied together. Later dynasties extended and expanded the wall.

The main part of the Great Wall is about 2,150 miles (3,460 kilometers) long. In addition, the side branches total another 1,800 miles (2,900 kilometers). On average the wall is 25 feet (7.6 meters) high. The bottom of the Great Wall is usually 25 feet (7.6 meters) wide. The top is a road paved with brick or stone usually 15 feet (4.6 meters) wide, where soldiers would stand to fight. Its watchtowers are usually 100 to 200 yards apart (90 to 180 meters).

The Great Wall is a testimony to human abilities to build and to wage war. The human cost for building the Great Wall was very high. Men from many families were drafted to work on the wall. Many died during their labors and were buried inside the wall. Today, parts of the Great Wall have been lost to erosion. Some sections have been rebuilt by the current government. The bulk of it was rebuilt and expanded during the Ming Dynasty and is now serving as a major tourist attraction. In 1987 it was listed as a World Heritage site by the United Nations agency, UNESCO.

— Andrew J. Waskey

Archaeology in the South American country of Peru has an extensive history that has uncovered the development of the largest native state to evolve in the Western Hemisphere, the Inca. The material representations of the Inca include monumental architecture, and ceramics and metallurgy craftwork from nearly a dozen separate and distinct cultures, each with their own history in half a dozen countries, all of which eventually came to be ruled by the Inca.

To uncover the prehistoric development of Peru, extensive cultural and archaeological research has been undertaken. The father of archaeology in South America is Max Uhle. Uhle has more time and research devoted to South American archaeology than any of his counterparts and was the first archaeologist

to embark on significant excavations in Peru. Contributions by other pioneering archaeologists like John H. Rowe, Walter Alva, and Julio Tello have helped to decipher the chronology of the region. They have also contributed to a prevailing attitude of cultural pride and patrimony, which has further enabled the exploration and interpretation of the rich history of Peruvian culture. This movement has led to native peoples' retention and retrieval of many of the collected artifacts. Today there is an international moratorium on the sale of pre-Columbia art that, if violated, can include incarceration and financial penalties.

Despite the renowned accomplishments of the Incas, they were not the first complex civilization of the region as their creation myth suggests. For example, on the shores of Lake Titicaca, the Tiwanaku culture flourished before the Inca found their capital in ruins. An obvious predecessor in specialized craftwork, Tiwanaku was home to monumental *stelae* or carved stone. Pachacamac at the mouth of the Rio Lurin and Chan, and the Chimor capital at the mouth of the Rio Moche, were also great cities the Incas could not claim. However, they all have cultural beginnings that reach back to the initial peopling of the continent. The oldest archaeological site in the region is Monte Verde. It is dated to 12,500 RC (14,800 BP). However, these dates are highly contested. If they are correct it would mean the human occupation of South America is pre-Clovis. There are more than a dozen dates from

this site and evidence of a successful hunter-gatherer lifestyle. Though Monte Verde is not fully accepted by the scientific community, there is a well-established chronology for development after the initial inhabitation of the continent.

Lithic Period: 10,500 B.C.–3500 B.C.

The Lithic Period (10,500–3500 B.C.) is characterized by hunting and gathering in the highlands and fishing on the coast. Sea levels had stabilized at this point and climatic conditions were similar to the present. Four distinct traditions typified the life-ways of Peru's inhabitants and their material developments.

The Northwest Tradition extended south to the Rio Piura and Chira. Rock was scarce in the region, so bone was used to make fishing implements. Some stone tools, such as axes, were found at the site of Las Vegas, where there is evidence of long-term settlement. The site had more than 30 camps and a trash midden that was 1 meter deep. The midden was later used as a cemetery and contained 192 secondary burials. Use of land animals, such as deer, is apparent, as is the evidence for bottle gourd cultivation. Las Vegas is 3 kilometers from the coast, but fish and mangrove mollusks from the sea have been found there.

The Paijan Tradition stretched along the coast from Rio Omo and Santa, and was defined by long, slender projectile points, which were likely mounted

on the hollow shafts of cultivated reeds and used as fishing spears. More than 4,500 artifacts were recovered from La Cumbre located on the north side of the Moche valley. This site included the typical foliate bifaced projectile points and side scrapers that were notched or denticulated.

The Central Andean Tradition persisted from the region of the Rio Santa to Chile and Argentina. It consisted of adaptations to deal with the diversity of the puna, the sierra and the coast. Sites of this tradition often contain willow-shaped projectile points. Pachamachay Cave,

Source: © iStockphoto/Dan Brandenburg.

which is located 10 kilometers from Lake Junin, at an elevation of 4,300 miles above sea level, has a faunal assemblage that is 97% camelids, likely vicuna. Vicunas are the wild ancestors of llama. This site included two phases. The first phase consisted of mobile hunter-gatherers and the second phase showed evidence of a longer, year-round occupation.

The Atacama-Maritime Tradition consisted of coastal fisher-folk with some leaf-shaped projectile points and stubby harpoon points. The south coast Ring site, located near the Rio Moquegua, shows evidence of year-round occupation. It contained a central plaza with a midden of shellfish that is 2 meters deep. Farther south, skeletal remains were recovered at the Asia site. Chemical analysis of these remains indicated a diet of 90% seafood.

The Chinchirro mummies are also found in this region. Dating from 8000 BP–3600 BP, 250 mummies in a life-like state of preservation were recovered. Removing the skin to reinforce the joints with reeds and fill the bodily cavities with grasses and wool created the Chinchirro mummies. Then the skin was replaced and sewn together. The mummy was fitted with a clay-modeled facemask and a wig. There is evidence, by way of repairs to parts of outer wrappings, that mummies were taken out and paraded during special ceremonies. Ancestor veneration is believed to be important during this time.

Preceramic Period: 3500 B.C.–1800 B.C.

Following the Lithic Period, Peruvian culture ventured into organized labor and agricultural development. The Preceramic Period (3500 B.C.–1800 B.C.) was characterized by increased sedentism, monument building and the tending of cultigens, especially industrial botanicals. There are four building traditions found in this period.

Complexes constructed in the Plaza Hundida Tradition had sunken courts that were large, flat-bottomed pits lined with masonry. Stairways in and out, on opposing sides, suggest that they were employed for ritual processions. Early in the period, these sunken courts were circular in form, but evolved into rectangular construction. They were often placed in front of larger platform mounds. Sites that have this style of architecture include La Galgada, Salinas de Chao, Piedra Parada, and Caral.

The Kotosh Tradition was sometimes combined with the Plaza Hundida Tradition. The detached,

one-room sanctuaries of the Kotosh Tradition were meant to accommodate a small congregation of people and were probably employed by religious leaders for private ceremonies. They contained central hearths from which burnt offerings have been recovered, and only one entrance. Many of these structures had carefully plastered floors, wall friezes, and ornamental niches, which were built into the walls. At the site of Kotosh, two of these structures flanked two large platform mounds, which reflect the dual moiety religious tradition of the region.

The Supe Tradition was responsible for the largest pre-pottery monuments located along the coast from Rio Chicama to Rio Chillion. At sites such as Huaca Prieta and El Pariso, flat-topped mounds were constructed as stages for ritual display. It is clear by their placement that large audiences attended events there. Several communities linked by religious or fictive kin organizations built some of these platform mounds. The Aspero site had 11 small mounds, two large mounds, and six major platforms. The two large mounds are called Huaca de los Idolos, where a cache of broken ceramic figurines was discovered, and Huaca de los Sacrificios, where two burials were discovered.

El Pariso is the type-site for the Paraiso Tradition with the largest pre-pottery masonry monument. Over 100,000 tons of stone had to be quarried to build nine complexes over an area of 58 hectare in the Chillion Valley. Dates from this site suggest that construction began around 200 B.C. and was continuous until 1800 B.C. At El Pariso, there were two elongated mounds that form a u-shape, with a central plaza. The central plaza had a sunken floor and was surrounded by a bench structure. There were also four circular pits with food remains that included seafood, jicama, fruits, achira, squash, and industrial cultigens.

Initial Period: 1800 B.C.–600 B.C.

The Initial Period (1800–600 B.C.) was characterized by an increase in monument building, settlement, farming and canal building for irrigation. On the coast, the Pariso Tradition of u-shaped monuments continued with an initial increase in the size of the constructions. However, around 900 B.C., a drought caused many of the coastal sites to be abandoned. The dual moiety organizations of Pacha Mama and Father Apus seems to heighten the importance of familial ties at this time.

Monument construction also increased in the highlands, although the ceremonial centers were on a much smaller scale. The domestication of camelids allowed the higher elevations of the Andes to be occupied, and herding replaced hunting. This period marked the beginning of production for utilitarian and painted ceramics.

Early Horizon: 600 B.C.–200 B.C.

The Early Horizon (600 B.C.–200 B.C.) was dominated by development at Chavin de Huantar and the Yaya-mama culture of the Lake Titicaca region. The Chavin site began around 800 B.C. and consisted of a large residential area located at an elevation of 3,177 meters above sea level, at the confluence of the Mosna and Wacheska streams. From 500 to 400 B.C. the prosperity of the city allowed the population of Chavin to double. It doubled again from 400 to 200 B.C., and consisted of up to 3,000 residents.

Chavin had far-reaching influence evident by the spread of iconography of anthropomorphic animals, which smiled and snarled, as well as dual staff god motifs. Other accomplishments during the florescence of Chavin included the innovation of heddle-weaving textiles of cotton and wool, as well as tie-dye and batik designs. Metallurgy was revolutionized at Chavin when gold was alloyed with copper and silver. The strength of this metal allowed for three-dimensional sculptures. This practice excelled in northern Peru.

From 400 to 200 B.C. there was a drought, and evidence suggests that people who lived closer to the ceremonial centers suffered less and ate better. This caused a separation of the social classes and the *kuraka* elites began to emerge. This is also evident from elaborate burials found on the coast and dated to this horizon.

Early Intermediate Period: 200 B.C.–600 A.D.

The Early Intermediate Period (200 B.C.–600 A.D.) is characterized by developments in farming and herding, as well as the rise of the politically complex culture of the Moche. Fortified villages emerged, and ceremonial centers outnumbered residential areas. The *kuraka* elites controlled governance and claimed special descent from founding figures. This system required extensive ancestor veneration practices.

Gallinazo pottery marked the beginning of this period and gave rise to the Moche styles.

During this period, the Moche practiced central governance from the capital of Cerro Blanco. Two enormous platform mounds were erected 500 meters apart. Huaca de la Luna and Huaca del Sol contained very rich burials. Residential and special craft production buildings were constructed between the monuments. Moche life is well depicted in their polychrome and variously molded pottery styles. Stirrup spout portrait pottery vessels are so numerous that full storerooms in Peruvian museums are filled with the unique examples of realistic facial replications, even of the sick and disfigured.

The richness of Moche craftsmanship is exemplified by a monument found near the village of Sipan, which is 420 meters (680 kilometers) northwest of Lima. Walter Alva was able to excavate three royal tombs here, which had not been looted. One of the burials, the Lord of Sipan, was a warrior-priest, and he was found fully clad in his formal regalia of gold, silver, and turquoise. Ceremonial knives, goblets, and pottery filled the tomb and led to a more extensive understanding of the Moche elite.

Middle Horizon: 600–1000 A.D.

The Middle Horizon (600–1000 A.D.) is characterized by the fall of the Moche and the rise of the Huari and Tiwanaku. This horizon had weather extremes of flooding and drought. El Nino patterns debilitated the Moche irrigation systems and moved massive sand dunes across many of the farming fields. The Moche capital was abandoned, and iconography at the huacas was replaced with staff god motifs. Sites that were still occupied showed evidence of a new obsession with storing food. A new strain of maize was present. There were rows of storage facilities at Pampa Grande, in the north, which became a new capital.

The cultures of the Tiwanaku and the Huari continued to evolve during this period. The site of Tiwanaku still has pieces of the elaborate gateways that were constructed there. The “Gateway of the Sun” has incised frieze decorations of the “Gateway God,” which is holding staffs of obvious Chavin influence. Tiwanaku culture appeared to be more conservative than the Moche. However, they excelled at ridge field agriculture and long distance trade. Great llama caravans moved textiles and ceramics beyond the Tiwanaku political sphere.

The Huari bordered Tiwanaku territory, but relations appeared to be peaceful. The Huari even erected a colony on top of the mountain Cerro Baul, which is in Tiwanaku's region. The Huari excelled at terrace farming and building irrigation systems. They were able to export their political ideas, as well as their iconography, by sending materials to build irrigation systems in other communities. The Huari staff god held ears of corn for his staffs due to the extreme importance of maize agriculture at this time.

Late Intermediate Period: 1000–1476 A.D.

The Late Intermediate Period (1000–1476 A.D.) is characterized by a decline in precipitation and another drought that lasted until A.D. 1500. Pastoralism increased at this time, and desert farmers began digging sunken gardens. Continued El Niño events devastated farming communities and contributed to a population decline. The beginning of the Inca culture is seen in the Killke culture of the northwest Cuzco Basin and in the Lucre culture of the southwest. The spread of corporate style ceramics from these regions is evidence of Inca hegemony starting to flourish.

The central and north sierra populations tried to resist Inca control. However, on the central and south coast, the Ichma allied with the Inca to defeat the Chimor. The Chimor capital of Chan Chan controlled 1,000 kilometers of coastal territory and aggressively contested Inca encroachment.

Late Horizon: 1476–1532 A.D.

The Late Horizon (1476–1532 A.D.) began with the rise of the Inca and ended with the arrival of Francisco Pizarro and his conquistadors in 1532. Before the Spanish arrived, the Inca had successfully controlled most of the region with statecraft unrivaled in South American history. The Inca only consisted of approximately 40,000 elites, but they conquered and controlled regions of the Peruvian Andes and Pacific coast for over 5,500 kilometers.

The Inca organized a cargo system, and annual ritual events were held. Ancestor veneration continued as the central religious organization. This incorporated a list of revered deities to be worshipped, such as Inti, the sun god.

The Inca instated a three-way tax system to control the people of the region. They employed *mit'a* labor,

or labor tax to continually erect and repair their monuments. On the agricultural front, they allotted farming families three separate plots of land to be tended, one each for the gods, the government, and family. Inca subjects were also made to pay tribute with fine textiles. Colors and decorations on textiles denoted their origins. Considered the navel of the universe, 40,000 people populated the capital city of Cuzco, but over 200,000 people lived outside of the city and supported it with their labor and taxes.

The region from Ecuador to Chile was known as Tahuantinsuyu to the Inca, or the Land of Four Quarters. Unfortunately, when Francisco Pizarro and the Spanish arrived in 1532, the Inca world was already in a state of upheaval. Millions of Inca and their subjects had succumbed to Old World diseases, especially smallpox. The death of the last Pre-Hispanic Inca emperor, Wayna Capac, had initiated a quarrel over the rightful inheritance of his position, and a civil war between Tumibamba, in the north, and Cuzco was under way. Medical historians have traced the first appearance of smallpox in the New World to Mexico in 1520. The disease traveled faster than the conquistadors that carried it.

This was the main contributing factor to Pizarro's victory. Despite the fact that he commanded only a few hundred men, he was able to dominate the Inca in very little time. Pizarro and his conquistadors kidnapped, ransomed, and finally murdered Atahualpa, one of the rulers that claimed kingship. This enflamed the Tumibamba-Cuzco civil war, and temporarily allied the Spanish with the Tumibamba.

Metallurgy, the extraction and mixing of natural metal ores, was so well-developed in the Inca state that when the Spanish reached Cuzco, conquistadors recording the events were in disbelief at the magnitude of riches, gold, silver, and precious stone that were encountered. Cuzco was said to be the home of the Inca sun god, Inti. The elaborate rooms of gold with rows of metallic maize, llamas, and shepards dedicated to Inti were so incredible that the conquistadors believed their homeland would think their accounts false. The riches that were taken after Cuzco was captured allowed for more conquistadors to come to Peru. Imported plants and animals brought diseases and took land from native resources. The degradation of the native people, land, and animals ensued.

PETRA

Ancient Petra (Greek: “rock”), located in the south-east corner of modern Jordan, was the capital of the Nabataeans, and later, a provincial capital of the Roman and Byzantine Empires. Today, Petra is one of the most popular tourist destinations in the Middle East.

Petra is situated in a valley bordered by mountain ridges on its east and west sides. The Siq, a narrow channel through the eastern mountain, forms the site's traditional entrance and is today the gateway tourists use to visit the site. Because water is always a scarce resource in Jordan, Petra's inhabitants managed the city's water supply using a sophisticated system of channels and cisterns to deliver water from two nearby springs to the city's cisterns.

Archaeological evidence and Classical period historical sources help reconstruct Petra's 9,000-year history. Small Neolithic settlements, such as Beidha, dot the region and attest to the region's early agricultural history. Starting around 800 B.C.E. in the late Iron Age, the Edomites of Biblical fame established a

village (Umm al-Biyara) on one of the high plateaus that guard the site. Petra saw a dramatic increase in settlement with the arrival of the Nabataeans from south Arabia in the late 4th century B.C.E. As the Nabataean capital, Petra was the center for an extensive spice trade that began in Arabia and stretched west to Palestine and north to Syria. Despite Pompey's success in conquering Petra in 63 B.C.E., the Romans permitted the Nabataeans limited autonomy in their political affairs. Many of Petra's architectural splendors were constructed at this time, namely, the tomb facades that line the city's cliff faces such as al-Khazneh (the Treasury) and ad-Deir (the Monastery).

In 131 C.E., the emperor Trajan annexed Nabataea onto the Roman Empire, making Petra the capital of a new province, Arabia Petraea. Under the empire, Petra continued to flourish: a colonnaded street, a theater, and other civic and religious institutions were installed. The Empire's conversion to Christianity occurred in 313, and the religion's popularity soon spread to Petra, where multiple churches were established. Under the Byzantine Empire, Petra thrived as the seat of a bishopric, despite a devastating earthquake in 363 that destroyed half the city. A shift in

trade routes and a second, even more devastating earthquake (in 551), led to a commercial decline and a dwindling population. Petra was eventually abandoned soon after Islam's introduction into the region in the 7th century. Aside from a Crusader fortress on the city's edge, settlement was limited to seasonal encampments of pastoral nomads until the early 20th century.

Petra was lost to Western visitors until 1812 when the Swiss explorer J. L. Burckhardt reintroduced the site to European audiences. Western explorers with more in-depth investigations of the ancient site followed Burckhardt. Scientific investigations of Petra began slowly after World War I, and increased rapidly after World War II, when Jordanian and foreign archaeological teams established projects throughout Petra. Sites were excavated not only to better understand the societies of their original architects, but also to rehabilitate buildings for presentation to public visitors. As a result, Petra attracts more than 1 million tourists a year, making it among the most visited antiquity sites in the Middle East.

PETROGLYPHS

Petroglyphs are a subset of the general category of rock art or rock graphics, which also includes pictographs and geoglyphs. Petroglyphs (petro-rock, glyph-carving) are man-made images or a series of geometric patterns that are carved, pecked, chipped, or abraded into stone using crude hand-held implements such as rocks, bones, antlers, and a wide variety of other objects as a chisel. Pictographs are created by painting on a rock using pigment materials such as charcoal, ash, lime, iron oxides, and ocher. The minerals were ground into fine powders and mixed with a

variety of locally available substances such as animal blood, resins, fats from animals, or seed to form a binder. Evidence of pictographs in open areas has disappeared due to weathering and erosion, but some have survived in protected areas such as caves, overhanging cliffs, and shelters. Geoglyphs are large surface images made by arranging rock debris or scraping away the surface area to reveal the underlying subsoil or rock surface to form the outlines of animals and human-like figures.

Found all around the world on a wide variety of surfaces from the desert varnish of basalts of the American Southwest to the glacier polished sandstones of the Alps, the common method of chipping on petroglyphs is to remove the outer weathered patina of the rock to reveal the usually lighter colored surface beneath. Rock that is very hard or contains an abundance of quartz is less suitable than softer limestones and other sedimentary rocks.

The images created on the petroglyphs vary from abstract combinations of straight, parallel, and wavy lines, crosshatches, diamonds, circles, dots, and zigzags, to anthropomorphs displaying human representations of stick figures and others with elaborately outfitted clothing and headdresses. Other graphics are zoomorphs, or animal figures. Like anthropomorphs, they vary from simple stick figures to complex scenes, and stylized figures with much detail. They differ depending on the location and animal life peculiar to the local environment, and from continent to continent.

Unlike hieroglyphics, petroglyphs are generally not a language but are images that record events, serve as historical markers, depict people and their tools and weapons, label geological formations such as springs, represent spiritual being and other mythical or magical beliefs, or serve some ritualistic purpose. Interpretation of many are yet to be categorized and their meanings to be determined.

Petroglyph sites provide a method of dating by a process of association with artifacts found in the surrounding area, for example, artifacts in campsites, villages, and hunting and food processing areas. On the petroglyph itself, dating can be accomplished by identification of the subjects, weapons, tools, style analysis, and any other objects depicted.

Petroglyphs are found worldwide with images peculiar to each region. Major concentrations appear on all the continents, but in particular in the American Southwest, Hawaii, Easter Island, South

Source: © iStockphoto/Jenni Morgan.

Africa, Middle and South America, England and Scotland, Europe in the Alps, France and Italy, and in Asia (China and Pakistan).

From early times to the present, petroglyphs present evidence that human beings utilized their surroundings to draw symbols and pictures to express their need to communicate ideas to their fellow man.

PEYOTE RITUALS

Peyote (*Lophophora williamsii*) Cactaceae is a spineless cactus that is native to central and northern Mexico and to the Rio Grande Valley of the southwestern United States, and that is used in ceremony among participants of the Native American Church.

When prepared correctly, peyote is a hallucinogenic drug, or a chemical substance that distorts the senses and produces perceptions of experiences that depart from reality. The top portion of the root of this greenish/gray cactus is cut and sun dried into “buttons” for consumption during a peyote ceremony. The dried button is ingested by mouth by being dampened with saliva and then swallowed. Mescaline and other biologically active compounds or alkaloids give peyote its hallucinogenic properties. Doses range from four to 30 pey-

ote buttons consumed during a peyote ritual, followed by hallucinations that grow in intensity three hours after ingestion. People report experiencing auditory, olfactory, and tactile hallucinations, an altered perception of time, and weightlessness. Historically, this plant was used as early as 2,000 years ago and early accounts from Spanish conquistadors reported their amazement at the powerful magic this plant possessed in inducing visions and for visioning of the future. During the 16th century the Chichimeca of Mexico consumed it before going into battle for courage and to have strength to fight their enemies. The Spanish sought to eliminate the use of peyote in an attempt to “civilize” the native populations; these efforts drove the use of peyote, along with its spiritual beliefs and practices, underground. Many of the specifics of peyote ceremonialism are strongly protected by the native people who continue to practice it today.

Among the practicing Peyotists or individuals who “follow the peyote road” are the Tarahumara Indians of the Sierra Madre Occidental of Mexico, who collect the peyote buttons for use and distribution to tribes in neighboring regions. The peyote religion spread in the United States in the 1900s around the turn of the century during the decline of the Ghost Dance, and subsequently became popular in the Southwest and Midwestern regions. The members of the Native American Church combine traditional ritual practices

with the belief in the Holy Trinity. The major precept of the religion is that God is a Great Spirit and Jesus a guardian spirit; however, beliefs vary considerably from tribe to tribe. Some see Jesus as a Native American culture hero while others believe in Peyote personified as God. The quarter of a million members value brotherly love, honor, trust, and the golden rule. They also incorporate some of the Ten Commandments, such as no adultery and divorce, and are especially adamant about abstinence from alcoholic beverages.

While these convictions are similar Christian doctrines, the ritual is uniquely Native American. Normally, the ritual begins at 8:00 p.m. on a Saturday and continues throughout the night and ends with a communal breakfast on Sunday morning. The belief is that the consumption of peyote allows for communion with the gods and the deceased, as well as giving power, guidance, and healing. The Ritual Chief, or Roadman, administers peyote to the congregation while peyote music, which often deals with subjects from the Bible, is sung in the background. The cult incorporates the use of feathers and rattles, bone whistles, and drumming as part of the ceremonial custom.

In the late 20th century, two Native Americans were dismissed from state employment because of their participation in the “drug cult.” The Supreme Court ruled against the right to use a controlled substance regardless of the religious context. However, Baptist, Catholic, Episcopalian, Jewish, Mormon, Methodist, and Muslim religious groups, as well as the American Civil Liberties Union, joined together to lobby Congress to pass the Religious Freedom Restoration Act. This was passed in 1993 and limits the government from intruding upon religious practices, which subsequently allowed the Native American Church to practice without interference.

PHILOSOPHY, DYNAMIC

Throughout the history of Western thought there have been key thinkers who have approached the world through a *process view*. The idea is that the world is constantly changing, both on its own and as people interact within it. These changing interactions and our understanding of reality and knowledge can collectively be called *dynamic philosophy*. Philosophy covers a range of subjects from metaphysics (the study of what exists) to epistemology (the study of knowledge) to ethics (the study of what is right). The reach extends to nearly every academic discipline, with specialized fields like psychology, natural science, and even comparative literature being rooted in philosophy. The dynamic aspect emphasizes the way the world evolves: how people affect and are affected by the world, how societies develop, how nature itself never stands still but is a continuing series of births and deaths—as Darwin identified, evolution. Anthropology has been influenced profoundly by this dynamic, or process, approach.

Ancient

The ancient Greek philosopher Heraclitus (6th century B.C.) is known for the saying, “You can’t step into the same river twice.” Change, he felt, was the one constant in life, the one guarantee. As a moment in time passes, a river is no longer the same, the water moving as it does in a flowing current from one place to another. People change as well, aging imperceptively from one moment to the next. Stepping into a river may not seem to be a life-altering event but the person is different nonetheless, because his experience has been enriched from the first step. Other pre-Socratic philosophers (the ancient Greeks prior to the time of Socrates, 469–399 B.C.) believed that such

elements as water (Thales of Miletus, 620–546 B.C.) and air (Anaximenes, 585–524 B.C.) were the underlying forces behind all life. Heraclitus lauded change, however, with the understanding of an underlying *logos*, or steadfast principle of reality that directs all things. The world in this view is in constant motion, but it is not chaotic; there is an order to the universe, even in strife, struggle, and what appear to be opposing forces or tensions.

The Roman poet Lucretius (99–55 B.C.) was a follower of Greek philosopher Epicurus (340–270 B.C.). The two men believed that change was essential to existence and that reality consists of an eternal collection of tiny atoms that move and change form to create the worlds, beings, and objects we recognize. Gods are not necessary and if they exist, they have little to do with the goings-on of humanity. When people die their atoms dissipate and return to the earth in a different form. Lucretius expressed these and other views in his epic Latin poem, *On the Nature of Things*. Unsurprisingly, he was influenced by tumultuous political times. He saw humans as being ruled by passions and hungers, but felt that they could control these urges through knowledge and cooperation. People could determine how to live their lives in a changing, adaptable way, rather than being locked into whatever was dictated by divine command.

Early Modern

Such theories fell out of fashion for several centuries during the Middle Ages and the spread of Christianity across Europe. Gottfried Wilhelm von Leibniz (1646–1716) was a German mathematician and philosopher who posed a different view of God than the anthropomorphized, omniscient, omnipotent God envisioned by the Roman Catholic Church. Like the atomists, Leibniz proposed that all existence was contained in individually moving, microscopic beings, or monads, and he saw God as the harmony that exists between their movements. This idea is different from that of his contemporary, Baruch Spinoza (1632–1677), who claimed that one underlying substance presented itself in individual beings by accident. For Leibniz the arrangement was no accident, but rather the harmonious effort of the independent monads, each empowered with its own intelligence.

There is debate as to whether Leibniz or Isaac Newton (1642–1727) was the first to develop modern calculus, but Leibniz's influence on the sciences can

be witnessed unquestionably in the concept of feedback. In engineering, for example, feedback is information that is collected as input and programmed into a device to generate a consequent output. Rather than a static flow of information in one direction, feedback allows the cycle to continue in what could be described as a dynamic process. Similar implications are felt in anthropology, such as economic systems and biological evolution that responds and shifts direction according to an interactive flow of information. In a lay sense, feedback can inform the decisions made by individuals and groups of people—and ultimately the development of societies. Leibniz's monadic system of independently functioning, intelligent units contains this element of interaction at its core.

19th Century

The capacity for reaction was central to the philosophy of G.W.F. Hegel (1770–1831), who saw world history as a continuous series of unfolding events, each responding to recent actions in an attempt to improve upon the flaws. Politically, the implications of this theory would explain reactionary movements in which an extreme approach to social policy inspires an extreme swing toward the opposite direction by the next generation. Totalitarianism prompts a desire to protect individual freedoms; an extremely liberal society is met with a return to traditionalist values. In a complicated and challenging application to metaphysics, Hegel proposed that existence requires an infinite interaction between the extremes of abstract idea and individual will, like an eternal pendulum swinging between thesis and antithesis in search of balance and pure harmony, or the synthesis of ideas. This dialectic approach influenced generations to come, including fellow Germans: Ludwig Feuerbach (1804–1872), who emphasized the connection between human needs and a desire to believe in God; Bruno Bauer (1809–1882), who interestingly abandoned his early “right” political thought for a later “left” movement; and Karl Marx (1818–1883) in the beginning of his paradigmatic political career.

Marx is known for his economic theories and his famous call to working men to unite in revolt against the wealthy, opportunistic *bourgeoisie* (the capitalists who, by definition, exploit and abuse the working class). His is a dynamic philosophy particularly because of the emphasis on struggle, but also because

he was not satisfied merely with studying the world; he wanted to change it. Marx accepted the dialectic Hegel proposed but rejected the idealist application of intellectually moving toward the abstract “real.” Life is material, and Marx’s application confronted materialism head-on, seeing human choices and confrontations as a result of the world rather than the world as a construction of the human mind. Marx believed that humans are not merely products of a pre-established biological blueprint, but rather, they adapt and respond to the events and circumstances of their world.

Friedrich Nietzsche (1844–1900) saw the world as founded on a type of creative energy in all matter and all living things, which he called “the will to power.” This will is beyond the desire to survive and preserve one’s own life; rather, it is the underlying influence that Nietzsche believed could explain all behavior and events in nature. Nietzsche detested what he called “slave morality” and the constraints imposed by the Christian view that God (and the afterlife) should be the human focus. In his series of parables in the collection *Thus Spake Zarathustra* (1885), Nietzsche showed how the *Übermensch* or “overman” could free himself from his chains by overcoming traditionalist strongholds by denouncing the old-world ideas of God and focusing on his own life, in the present, to construct his own set of morals and ideals (thus the often-misunderstood phrase, “God is dead”). Again, like Hegel’s dialectic, there is a dynamic exchange as the slave becomes his own master, harnessing the power of his will. Nietzsche presented the overman as the ultimate state from which early “human” apes were transitioning as a spiritual journey with implications for ethics, politics, and religion.

A literal evolution from ape to human was proposed decades earlier by Charles Darwin (1809–1882), who in *The Origin of the Species* (1859) presented the concepts that would forever change science, philosophy, and every field in between. Having observed fossil patterns that indicated change across generations in both plant and animal species, Darwin proposed his theory of biological evolution whereby modern humans could be traced as descendants of other animals. This undermined the authority of the Church which for centuries had taught that man and woman were direct creations of God in God’s image. If humans evolved from apes, then the implication was that God’s image was that of an ape or earlier animal—amphibian, fish, or even insect. If an ape is

clearly inferior to humans, then evolution seemed to propose God’s image as a creature less developed than *homo sapiens*. Darwin’s theory of evolution was met with exactly the reactionary social dynamics Hegel and others had identified. Darwin began his studies as a natural scientist observing sea life and South American vegetation. Perhaps due to sensitivity toward the impact such claims would make, Darwin took years to expand his observations to the point of including humans within this potential to evolve. Nevertheless, change was integral to life, Darwin argued, both in common descent through evolution and the concept of natural selection. Because nature is dynamic, certain traits can prevail or be repressed. Weaker species eventually die out or become stronger through adaptation. Darwin’s theory makes use of Leibniz’s concept of feedback as the world and the beings within it constantly interact, compete, learn, and evolve.

Darwinism often is reduced to “survival of the fittest,” a phrase actually termed by English philosopher Herbert Spencer (1820–1903). Spencer’s work established evolutionary change as the foundation of the social sciences, applied specifically to sociology and psychology. Human interactions, like genetic biological traits, work in such a manner as to ensure a type of natural selection within social groups, Spencer claimed. Some people are better equipped to deal with life’s misfortunes; some human societies will naturally conquer others by superiority or force of might. Spencer’s theories developed into “social Darwinism” which, although belied by the name, was not specifically endorsed by Darwin himself. Social Darwinism extended evolution to the study of human culture and toward a controversial justification for abandoning the poor and the members of society most prone to disease. Weak people could contaminate the gene pool, so in its most extreme form, social Darwinism maintained that only the strongest of the species should be allowed to reproduce. The distinction between descriptive theory and prescriptive plan for ethics became blurred. If it was natural for the strong to overpower the weak, then it would be unnatural to resist the domination that was inevitable.

20th Century

The American philosophical movement of pragmatism emerged around the same time Spencer’s theories were being integrated into social policy, and

pragmatism emphasized the involvement of the human intellect in developing a better society. This is where the similarities end. Pragmatist John Dewey (1859–1952), known for his educational philosophy, felt that the attainment of knowledge was an ongoing process, not something that children would learn once according to permanent and absolute principles of reality. Rote memorization does not engage the learner; for an experience to be truly valuable and consequential it should involve active participants who direct their attention toward improvement and toward recognizing their roles as individuals within the larger society. Dewey was not afraid of committing to an idea such as atheism, but he emphasized the continual search for truth through the process of refined experimentation. Earlier pragmatists Charles Sanders Pierce (1839–1914) and William James (1842–1910) directed this active approach to scientific inquiry toward the disciplines of mathematical logic and psychology, respectively.

The French philosopher Henri-Louis Bergson (1859–1941) exchanged ideas about consciousness with James, and both were interested in the intuitive energy that drives the functions of the mind. This interest informed the rejection of intellectualism as well as the mind-body dualistic separation that perplexed such philosophers as René Descartes (1596–1650). Experience, rather than pure logic, is the appropriate means for seeking the truth about the world. The spiritual element, however, the *élan vital* or vital force of the mind, is what Bergson saw as responsible for the evolution of living things. Like Nietzsche and Marx, Bergson proposed conflict as being inherent to life: inorganic matter in a battle against creativity, or, more specifically, the way in which beings are able to persist across time while continuing to evolve. Intelligence is a unique phenomenon among humans because of a decreased capacity to respond to the environment purely according to instinct, as is sufficient for other animals. It is by returning to this instinct that humans can overcome the emphasis on intellectual pursuits which only further remove the living being from his recognition of true knowledge and existence. Bergson's theories oppose the empirical versus pure intuition model proposed by Immanuel Kant (1724–1804) as an irreconcilable rift between perception and true reality. Rather, through intuition Bergson saw a means of explaining the simultaneous change and apparent persistence of life.

Alfred North Whitehead (1861–1947) also rejected Cartesian mind-body dualism and developed the concept known as *process philosophy*. Like Bergson, Whitehead recognized reality as a succession of events maintained by experience, rather than as individual apprehension of existing material objects. Interestingly, this view allows for the possibility of God as the creator of the possibilities of experience; it is individual will, however, that determines direction and choices. The world is constantly evolving and cannot be contained within a static understanding of what exists. Whitehead's metaphysical conception led to the development of process theology, whereby God contains all other existence, and necessarily changes as free will determines new paths of experience. There are essential elements of God, such as goodness, that remain eternally steadfast, but the world as it is experienced is subject to change by its nature and by the experiences of the beings within it. Immortality is through God, but God as the perfect being must allow for the possibility of change, rather than imposing an infallible view of perfect existence created by force.

Pierre Teilhard de Chardin (1881–1955) was both a theologian and a paleontologist who embraced the marriage of biology to spirituality found in Bergson's *l'Évolution Créatrice* (*Creative Evolution*, 1907). Teilhard's conviction was that evolution was orthogenetic and teleological in nature; that is, human life was part of a larger and linear progression of life encompassing the whole universe and moving toward perfection. Unlike modern evolutionary synthesis or neo-Darwinism, Teilhard did not believe that the changes across generations were mere accidents. He acknowledged the interaction of the beings in nature and their potential for affecting the environment, but believed this movement was in a positive direction, toward improving overall species and the world. This is not unlike the underlying harmony Leibniz proposed as the collection of movements among the monads. Teilhard's geological excavations in China were more warmly received by the Roman Catholic Church than were his religious lectures (Teilhard was an ordained Jesuit priest); his theological writings were barred from publication, he was relieved of his lecture privileges, and he was banished from his homeland of France for philosophical differences with the Vatican. Teilhard was part of the 1929 group that discovered the Peking Man, *homo erectus* fossilized remains from the Pleistocene era. Paleontology ultimately exposed the weakness of the orthogenetic

theory when no mechanism could be determined to fully explain the inconsistencies that appeared among different groups of fossils; there was no clear, single, linear plan to explain the evolution of all life forms. The 1950s discovery of DNA genetic structure further emphasized that the direction of evolution was subject to modification between generations and not exclusively committed to a single goal. Nevertheless, Teilhard's approach was to unite science and theology by emphasizing the ways in which spirituality can be found in the material world, because both are part of the common totality of existence in the universe.

PHONETICS

Phonetics is the scientific study of speech sounds. Unlike phonemics (the study of the organization of speech sounds into a linguistic system), phonetic studies can be carried out without necessary regard for the language system within which they may be found. That is, researchers making a phonetic inventory of

the sounds of a language, say English, will note that speakers of English produce sounds such as [t] and [t^h]; they may not be concerned with whether these sounds are contrastive in English (they are not).

Traditionally, researchers have used three approaches defined by the types of problem under investigation. Auditory phonetics is the study of the perception and processing of speech sounds. This branch of phonetics often makes use of highly specialized equipment that tests people's ability to hear or to distinguish between particular speech sounds. Acoustic phonetics is the branch of phonetics that deals with the physical properties of sound waves moving through the air, as recorded by instruments such as a sound spectrometer. Articulatory phonetics is the study of the gestures, made in the vocal tract, that result in the production of speech sounds. Traditionally, anthropologists have been most interested in this branch because it enables them to inventory the sounds of a previously unwritten language, in preparation for making a phonemic study of the language, and also to facilitate the recording of linguistic data.

Speech sounds are produced by moving air through the vocal tract, which extends from the larynx to the lips and includes the nasal cavity. Speech sounds are divided into two natural classes: vowels and consonants. Vowels are produced by passing air through the tract without obstruction; vowel quality depends on the positioning and tension of the tongue muscle, and by presence or absence of lip rounding. For example, [u] (the vowel in *boot*) is high, back, tense, and rounded; [a] (*cot*) is low, back, lax, and unrounded.

Consonants are produced by obstructing the air in some way as it passes out of the throat. Consonants are usually described in terms of the state of the larynx (voiced or voiceless); the place of articulation (bilabial, labiodental, etc.); and the manner of articulation (stop, fricative, nasal, etc.). For example [b] is a voiced bilabial stop; [f] is a voiceless bilabial fricative.

Lieberman and Crelin attempted to determine the speech sounds that Neandertal hominids were capable of making by making a computer-generated model of their vocal tract, and then using this to determine the sounds they could have produced. Although they probably underestimated the Neandertals' speech ability, this was an innovative and important use of acoustic phonetics.

The term phonetic is sometimes used by English speakers, especially those in the educational community, to refer to spelling which is based on sound rather

Source: © iStockphoto/Vasiliki Varvaki.

than on traditional orthography. This usage is erroneous; the proper term is phonemic or phonological spelling (see phonology).

Phonetics has probably gained its widest currency in contemporary anthropology as the source for the term *etics*.

PHONOLOGY

Phonology, also called phonemics, is the study of the organization of speech sounds into a linguistic system of contrasting elements called phonemes. Unlike phonetics, phonology must account for native-speaker judgments as to what is contrastive and what is not. There are two broad approaches to this study: one regards phonology as a level of structural organization of a language; the other, developed more recently, considers phonology a component within the generative grammar of a language.

Any two sounds of a language contrast if they can be found in a minimal pair, such as the [f] and [v] of English *fat* and *vat*. Such sounds belong to separate phonemes, usually represented between forward slashes (/f/ and /v/) to distinguish them from their phonetic representations between square brackets. The word phoneme is from the Russian *fonema* via French *phonème* as used by Ferdinand de Saussure.

Phonological analysis organizes sounds that do not contrast into phonemes. For example, in standard Spanish [s] and [z] are allophones of a single phoneme /s/; the phoneme is predictably pronounced [z] before voiced consonants (*mismo* = [mizmo], *desde* = [dezde]) and [s] elsewhere. In this case the allophones are said to be in complementary distribution. This relationship between [s] and [z] can be captured in a phonological rule:

/s/ → [z] / __ [consonant +voice]; [s] elsewhere

The rule, expressed in words, reads: The alveolar fricative phoneme is pronounced voiced, preceding a voiced consonant, and voiceless in all other environments. The use of /s/ rather than /z/ to represent the phoneme is determined by the fact that [s] is the principal or default allophone.

Sounds may be allophones of a single phoneme, but not be predictable by a phonological rule; the allophones are then said to be in free variation. For example, in some varieties of Creole English, as spoken in the West Indies, the vowels [i] and [ɪ] (the vowels of standard English *sheep* and *ship*) are allophones of one phoneme /i/ in free variation, making *sheep* and *ship* unpredictable homophones in those language varieties.

It is important to emphasize that a phoneme, like Spanish /s/, is not a sound; it is a mental “concept”

that is pronounced as one of its allophones when it goes through whatever phonological rules apply. The “concept,” however, is semantically empty, meaning that just as bricks can be combined to build any number of kinds of useful structures, phonemes can be combined and recombined to form any number of meaningful constructions (morphemes, words). This is expressed by Charles Hockett’s dual patterning design feature.

In addition to vowels and consonants, sometimes referred to as segments, suprasegmental features such as length, stress, nasalization, tone or pitch, and intonation may also be contrastive. For example, in Latin a contrast exists between short and long vowels resulting in pairs such as /os/ “bone” and /o:s/ “mouth.”

Learning and recording data in previously unwritten languages has been an important component of anthropological fieldwork. To this end, phonology (together with phonetics) has given anthropologists an analytic procedure for, in Kenneth Pike’s words, “reducing languages to writing.” This procedure has provided a model for scientific analysis of human cultural patterns.

PICTOGRAPHS

Pictographs, sometimes referred to as pictograms or pictoglyphs, are written, painted, or engraved signs that express ideas or meaning in the form of pictures. In a pictograph, the sign takes the form of the object it is supposed to represent. These physical resemblances can be highly iconic—such as a picture of a

specific animal—or more abstract—as in a wavy line representing a river, or some inverted v-shapes standing for mountains. Even in modern cultures pictographs are ubiquitous, as seen, for example, on the doors of most restrooms indicating gender.

It is likely that writing developed out of the earliest drawings made by humans. For example, we can “read” the famous pictures found in the caves of France and Spain, which date back to the Upper Paleolithic, some being perhaps 20,000 or 30,000 years old. But it is unknown whether the intent of these illustrations was to convey information or narrative, express artistic emotion, or to be used in acts of sympathetic magic. Over time, we find signs that obviously *are* being used iconically—but not aesthetically—to express concrete things or incidents (in other words, true *pictographs* as opposed to *pictures*). These pictographs are usually more frequent and less complex than the more elaborate paintings, and some regularity might be noted in how the signs are formed or repeated. Pictographs exist throughout the world, both old and new, and on every continent. Some of the most famous are found etched in stone in the American Southwest, where they are usually called petroglyphs (Greek for “rock carving”).

Pictographs are sometimes called a system of picture-writing, but this is actually a misnomer. If we define a writing system as something that captures spoken language on some medium (like paper or stone), pictographs would not fit this definition. This is because pictographs represent objects in the world and *not* the spoken names for these objects. Thus, in using a pictographic system, we are not actually *writing down* a language, but representing data directly. However, what was occurring was idea-transmission, which was a necessary pre-condition for a writing system to develop.

Presumably, pictograms may have developed into ideographs, or ideograms, as they became more stylized and abstract. For example, the sign for “sun” in ancient China was a circle with light rays coming out of the middle. Over time, the circle became oval, and then a rectangle, and the rays became a single horizon line. Thus, this is today’s Sino-Japanese character for sun. Ideographs differ from pictographs in that they lack—due to stylization—the usual obvious iconic connections to external reality. Ideograms have been thought to be transitional between pictograms and logograms. (Logograms are written signs that *do* represent words or morphemes in a language, but give no indication as to how they are to be pronounced, such

as everyday numbers or mathematical equations which will be read in different ways depending on the language one speaks.) However, most scholars agree that no writing system has ever really been ideographic, though many contain ideographic elements. Last, while many believe in a pictographic origin of writing, work on Sumarian cuneiforms suggests that signs using abstract shapes might also have led to the development of writing.

PIKE, KENNETH L. (1912–2000)

Dr. Kenneth Lee Pike was born in Woodstock, CT, in 1912. He earned his B.A. in theology from Gordon College in 1933. After being denied missionary work in China, he joined the Summer Institute of Languages to study Amerindian languages in Mexico in 1935. There he learned to speak Mixtec directly from Mixtec speakers without the aid of an interpreter. In 1937, Pike began his doctoral study of linguistics at the University of Michigan where he studied under Edward Sapir in the Boasian cultural relativism tradition. While engaging in his doctoral research, Pike, and his wife Evelyn, lived among the Mixtec. Together they developed an alphabet for the purpose of translating Mixtec language into literary forms. In 1942, Pike earned a Ph.D. in linguistics and became president of the Summer Institute of Languages. He published the *Mixtec New Testament Bible* in 1951.

Pike divided his time between the Summer Institute for Languages at the University of Oklahoma, where he was its director, and the University of Michigan where he served on the faculty for 30 years in various capacities including professor of linguistics, chairman of the department of linguistics, and the director of the English Language Institute. Pike was also a pioneer in the field of English as a second language, more commonly known by its ESL acronym.

In 1954, Pike introduced the theoretical orientation of emic and etic contrasts in understanding linguistics and culture. The terms are used by the social and behavioral sciences to examine two kinds of data concerning human behavior. Linguistically, emic is analogous with phonemics and etic is analogous with phonetics. Phonemics is the subjective study of the meaning in linguistic sounds. Phonetics is the objective scientific study of linguistic sounds. According to Pike, native members of a culture are the exclusive judges of the precision of an emic description. They can identify psychologically distinct units of sound not recognized by

Source: © iStockphoto/Henry Lucenius.

outsiders. Only insiders can provide the data for examination of language at the level of meaning.

Conversely, phonetics is the objective point of view of language. It is the view of the outsider or investigator, who controls the legitimacy of an etic explanation through empirical investigation and the production of generalizations. Etic methods can be verified and replicated. They provide understanding that is meaningful from a scientific perspective. Pike was known for his studies of aboriginal languages in Mexico, Peru, Ecuador, Bolivia, Java, New Guinea, Ghana, Nigeria, Australia, Nepal, and the Philippines.

The etic and emic cognitive framework is also useful when applied to cognitive anthropological field research. It views culture as mental processes. In participant-observation, anthropologists obtain the etic view by remaining objective and detached. The emic perspective is learned by involvement. Emic models of culture reveal how natives understand their society. Pike argued that seeing the emic perspective challenged ethnocentrism and promoted cross-cultural understanding and respect.

Pike was internationally respected for his linguistic theories, research into language development, contributions to poetics, and creation of tagmemics. The theory of tagmemics makes the distinction between phone and phoneme in phonetics and phonology at higher levels of linguistic analysis. Pike developed this concept to aid in the analysis of Central and South American languages. It identifies strings of language units that can fulfill several functions. Both semantic and the syntactic functions are used to identify tagmemes. He also applied the concept to field theory.

Pike incorporated his strong Christian faith into the Summer Institute of Languages (SIL). SIL was a non-profit organization that focused on the translation of the Bible into preliterate languages. Pike was the President of SIL International from 1942–1979, and President Emeritus from 1979–2000. At the time of his death, Pike was involved in many professional organizations including the National Academy of Science, the Linguistic Society of America, and the American Anthropological Association. He was also President Emeritus of the University of Michigan. Because of Kenneth Pike's large impact in the field of linguistics, he was nominated for the Nobel Peace Prize for the 15 consecutive year, ending in 1966. He died on December 31, 2000.

PINKER, STEVEN (1954–)

Steven Pinker is an experimental psychologist who has argued that human capacities for speech and abstract thought are based on evolved components of our brain that are not shared by other primates, and that much of human behavior results from evolutionary adaptations. Pinker was born in 1954 in Montreal, Canada. He earned his doctorate at Harvard in 1979, and spent most of his career at the Massachusetts Institute of Technology. He is currently a professor in the Department of Psychology at Harvard University. His experimental research has focused on language acquisition by children. He has also succeeded in making psycholinguistics and evolutionary psychology accessible to non-specialists by writing and speaking for general audiences.

In reaction to behaviorists like Burrhus F. Skinner, who insisted that the human mind was “a blank slate” at birth and that psychology was unrelated to biology, evolutionary biologists such as Edward O. Wilson and Richard Dawkins argued that many human behavioral tendencies are a product of natural selection. Evolutionary psychologists subsequently proposed that emotions such as guilt, anger, sympathy, and love all have a biological basis. In 1998, Pinker argued in his book, *How the Mind Works*, that biology partially explains our moral tendencies. The evolutionist Stephen Jay Gould firmly rejected this approach, calling it “biological determinism,” arguing that selection operates on individuals not genes.

Pinker's arguments are based on the notion that most human cognitive tasks evolved as distinct modules, especially the components of language. This

was based on Noam Chomsky's view that humans are genetically predisposed to learn language, and thus languages are fundamentally similar. In particular, phonology and syntax are produced by distinctly evolved modules, are similar across cultures, and are missing in other primates. Evidence for modularity includes the innate and rapid acquisition of specific language skills by children, the tendency for brain lesions and genetic mutations to selectively impair cognitive functions, and brain imaging that revealed areas dedicated to specific tasks.

Terrence W. Deacon, Phillip Lieberman, John R. Anderson, and others argue against modularity, claiming there was not enough evolutionary time for individual modular selection, genetic differences between humans and other primates are insufficient for explaining different brain structures, and there is no evidence for a central processor required to coordinate modules. Lieberman, Merlin Donald, Kathleen Gibson, Stephen Jessee, and others argue that brain mechanisms used for speech result from evolutionary changes to pre-existing devices. For example, syntax may derive from precise hand gesture and motor control common to higher primates. Pinker's ideas place him in the larger debate between discontinuous language evolution (language is qualitatively different from other primate abilities and must require special devices) and continuous evolution (humans possess expanded versions of the same devices that other primates have).

Pinker's contention that language and behavior are mostly genetically controlled contradicts the theory of linguistic relativity proposed by Edward Sapir and Benjamin Wharf. His work also impacts philosophical and ethical debates regarding human free will. Future experimental research and rapid advances in brain imaging technologies may help identify unique anatomical structures dedicated to specific cognitive tasks as predicted by Pinker.

The major thesis of political anthropology is that politics cannot be isolated from other subsystems of a society. Political anthropology has defined its interest in how power is put to use in a social and cultural environment. Power is defined as political influence to accomplish certain aims. Through cultural interpretation, the political culture defines certain goals as acceptable. Political systems operate within a historical setting. The ability to make and enforce decisions is the basis of power, and power is what political anthropologists study. Political anthropology investigates the everyday experiences of people as they are shaped by their economic position in a particular society, and the world economy that molds most political issues.

Political Theory and Structural Functionalism

Structural functionalism is the study of how the separate parts of a society interact to form a cooperating whole; this is called synchronic. Synchronic theory characterizes the most important goal of any cultural element as the harmony of the society as a whole. The political anthropologist studies the complex interaction of mutually interrelating parts. History is not the focus in these studies. The society is studied from a holistic viewpoint. The interaction of the subsystems or institutions to maintain the equilibrium of the whole becomes the focal point of research. The political institution interacts with kinship, family, religion, and the economy as a single mutually supporting system. The major theme of each institution is the adjustment to long-term equilibrium.

Political culture is comprised of the core values of a society. Political action happens through the use of symbols, and these are defined by the political culture. Manifest functions are the stated utility; the latent function is the hidden, and more real, reason for any observable fact occurring in a social situation.

The heyday of structural functionalism was pre-World War II British anthropology. Fine examples include E. E. Evans-Pritchard's *The Nuer*, and *African Political Systems*.

Pluralism

In the United States a theory closely related to structural functionalism was pluralism. Pluralism asserts that democratic state societies are made up of a collection of competitive interest groups in conflict with one another. The state balances these groups through compromise. The government is the neutral referee. Each group has about equal influence on public policy.

Process Theory

How are the public goals accomplished? What are the quantity and the style of power used by various competing groups in determining public policy? To answer these two questions, the study of competition between rival groups is central.

Societies are studied in their historical context, i.e., *diachronic*. Change is a constant in all social settings. *Parties* (teams that compete) vie for power in order to define public goals and determine public policy. In this it is assumed that conflict is constant. Process Theory studies take place in a *political field*. A political field is any area in which a political contest takes place. The competition is over political power. *Power* is the ability to influence public policy in the face of opposition. Power can be *independent* or *dependent*.

Independent power is the direct power of an individual or group. In *egalitarian societies* this power is based upon either personal charisma or specialized knowledge. In *centralized societies* power is vested in individuals that occupy particular offices. *Dependent power* is defined as the transfer of powers by one individual or group to another individual or group.

Legitimacy is a support coming from the political culture. There is consensual power within the political culture even if a large group of people disagrees with certain aspects of the leadership or their policies, if the greater essential quality of the political structure is still seen as valid. The other source of power is *coercion*, in which the authority of the office holder is supported by force or the threat of force. In state societies, legitimacy is always backed by coercion. Only in nonstate societies is it possible to have legitimacy without coercion. Both sources of power can be used in the conflict over power.

Action Theory

Action theory is an expansion of the Process approach. There are, in most societies, teams called political parties that compete for power. Each team has its leadership, which manipulates symbols of the political culture to gain and maintain power.

This competition occurs in the political arena in which rules govern the contest. These rules are interpreted, explained, and then rearranged according to a specific agenda. Political core values are used to explain these rules in order to strengthen one or another team's claim to power.

All equilibrium is unstable and temporary. Continual readjustment is necessary while the tournament continues. Teams mobilize their political capital for a showdown, followed by the reestablishment of an unstable equilibrium. In this game normative rules represent the core values of political culture. These rules are always vague and abstract. The pragmatic rules are the real rules with which the game is really won.

The top leaders become symbols of their party. Leaders can either be *moral* leaders or *contract* leaders. A moral leader represents the shared normative ethics of the group. Moral leaders tend to be dogmatic and rigid, whereas the contract leader leads an alliance of diverse individuals that hopes to profit personally from victory.

Over the long run, teams in a stable society are about even in strength. Most parties encapsulate smaller parties within them. Within parties, conflicts also exist and are resolved in broadly similar ways. Even in a one-party state there are political contests. Political change often is repetitive as power is passed back and forth between the teams. At times, normative rules are reinterpreted and pragmatic rules change; the teams appear to stay the same as they adapt to a changing social environment. Only in an all-out revolution does change require a replacing of both sets of rules.

Elite Theory

Classical elite theory asserts that all societies are in fact ruled and controlled by a small ruling elite. The state, or even tribe, is the political tool of this elite. The Elite Theory states that the majority of people are incapable of self-rule. The leaders govern because the masses need them to.

Vilfredo Pareto (1848–1923) claimed the ruling elite was in fact made up of superior individuals, with the will to power. History is the “circulation of elites.” The elites incorporate a small number of superior individuals from the masses in order to continuously maintain the vitality of the ruling class. Periodically, there is a breakdown of social equilibrium. When this happens, the old ruling elite is overthrown, and replaced by a new elite.

Gaetano Mosca (1858–1941) stated that the superiority of the political elite is that they have the virtues needed to rule. Elites have the extensive contacts, which determine their type of society with its political structure and culture. Elite is not a closed class; they continually incorporate the best from the masses.

Robert Michels (1876–1936) wrote that the bureaucratic organization results in the arrangement of elite command. The bureaucratic organization requires a specialized staff with skills that are difficult to replace. Both leaders and staff members require a specialized education. This complex organization requires highly structured authority to orchestrate its successful operation.

C. Wright Mills (1916–1962) stated that the power elite is composed of those who command the leading hierarchies of U.S. society. This includes top managers in big corporations, the top government officials, and the leaders in the military. It is in the reciprocal collaboration between these three elite groups that the power in American society rests. Power in U.S. society is derived from these linkages. Often the same individuals are leaders in several hierarchies. Business is the first in importance, while the strength of the military is growing rapidly.

William G. Domhoff, still very active today, writes that, in the United States, the upper class dominates the government. They form a close-knit group based upon control of corporate stocks, trust funds, government, and academic institutions. They organize themselves through marriage selections, private schools, exclusive clubs, summer resorts, debutante events, and corporate boards. They form a select group of intermarrying kinfolk, whose power is based upon control of business and political institutions of society.

Instrumentalist/Structuralism Debate

The *Instrumentalists* assert that the ruling class of capitalist society is able to dominate the apparatus

of domination of society because it controls the economy. On the other hand, *Structuralism* contends that the state power is independently operated in a way that benefits the capitalists, or any upper class. The function of the state and the dominant class coincides by necessity.

Albert Szymanski (1942–1985) writes that the state is an instrument of exploitation of the economically subordinate classes, and is secured for the benefit of the dominant class. The political, ideological, and economic environment insures that economic social relations and ideological hegemony are preserved. State managers have very limited options. The state is controlled by the upper class by both direct and indirect means. The logic of capitalist economic relations, reinforced by capital's ideological hegemony, dictate the policies that the state must follow.

The institution of the state is always a political tool of a certain class or classes. Under capitalism the class that owns and controls corporate capital clearly dominates the state either directly by providing leadership, or indirectly by defining the issues. Within capitalism the state is central to stabilizing all of society for the capitalist by insuring the profit-making process is the main economic issue, and by increasing economic productivity of the labor force and the growth of the economy overall.

Postmodernism openly questions the legitimacy of the modernism of progress, rationalism, science, and technological progress. Science, objectivity, and grand theory are all seen as a privileged narrative that misses the point that reality is subjective, relative, and socially constructed.

Social Organization

The physical environment and the type and level of technology influence social organization. When a people, through their culture, adapt to their environment they change that environment. Population pressure, technology, physical environment, social environment, and political and ideological culture interact in a mutually self-reproducing way. This interaction implies a structure and a relationship of change. This is a system, which means that if we know elements of the system, alternative elements can be suggested. The environment and technology as related to subsistence seem to be the most important. However, the parts are interrelated and measurable with statistical probability.

Nonstate Society

Bands are small communities usually consisting of between 25 to 150 individuals. The nuclear family is the primary social organization. Bilateral kinship is the most common form found in band society. The size of the bands in band society changes through time, depending on the type of resources that are being exploited. Leadership within the bands is, for the most part, temporary and situational. For most, political equality is the major social organization. Coercion, laws, and restriction to major economic resources are very rare among band members. There is little specialization of skills that would lead to a permanent division of labor. This means there is usually no religious priesthood or permanent political leader. The division of labor is based upon gender and age. Custom is the ideological glue that holds the society together. The economy is primarily foraging from the local environment. Trade is very minor. However, reciprocity is the major form of distribution. A typical example is the Shoshone and Paiute tribes of the Great Basin of North America before contact with other tribes or Europeans.

Tribal society is based upon the village or clan. They are horticultural or pastoral based on their means of subsistence. Communal ownership of land or herds is the most common form of economic control. Distribution is based upon reciprocity. Trade is minor, but more developed than among band societies. Tribes are egalitarian communities in which power is decentralized through a lacework of personal and group relations. Leadership is charismatic without coercive authority to enforce decisions over group opposition. The right to use force is kept within the lineage as a communal claim. The groups depend on domesticated food supply more than wild crops. There is very little political, religious, or economic specialization. Tribes are generally egalitarian. Clans are of a unilineal kinship organization, either matrilineal or patrilineal. Pan-tribal sodalities unite clans into larger organizations. These include voluntary societies, age grades, and segmentary lineage systems. Examples are the Nuer of 1940, or the Iroquois of the 18th century.

A *chiefdom* has a centralized authority. The office of the chief is moving closer to a continuous position. Generally only members of a certain clan or lineage in the larger kin group are eligible to obtain, by succession, the office of chief. Membership in any clan or

lineage of the ethnic group is unilineal. While no real class divisions exist, this is a ranked society. Clans and individuals are both ranked, some earned and some inherited. The authority is one of minimum power; the amount of coercion a chief can use is small. Economically, the chief is the great provider. The chief is in charge of a system of redistribution. Taxes are collected in some sort of desired goods to be returned in a ceremonial "give away," maintaining the group solidarity and uniting the clans under the chief of the kinship group. An example of a Chiefdom includes the Ashanti of Africa before British colonization.

A *state society* is a society that is sharply divided into social and economic classes. Membership of the state is defined by residence within a territory. Within these borders all residents are subject to a single authority, which consists of a small elite monopolized political power. There is a formal body of laws and courts, and a monopoly by the state officials on the legitimate use of force. How and why states first emerged is debated openly.

The *Internal Conflict* theory (Lewis Henry Morgan) of the state begins with studies of how ancient people lived in small and egalitarian communities. Resources were equally shared; then technological innovations developed. This allowed a surplus to develop. A class of non-producers appeared, along with private property. Access to resources became more restricted. The elite then created the state to protect themselves from the producers who created the wealth.

According to the *External Conflict* theory (Herbert Spencer), the groups with the strongest military survived. The stronger army conquered the weaker one. This external threat required a coercive body, called government, to arise to meet this outside peril.

In the *Environmental Circumscription* theory (Robert Carniero), the State Societies developed in areas that were circumscribed by their environment. Because of the fact that, since war is nearly universal, it is more likely to lead to population dispersal than the formation of the state, Carniero asserts that State Societies could only arise in areas in which mountains, deserts, or seas surrounded good agricultural lands, making dispersion of the population nearly impossible.

In the *Hydraulic Civilization* theory, Karl Wittfogel claimed that, to increase farm production in river valleys, large complex irrigation systems were developed, requiring several villages to cooperate in maintaining a controlled water supply, supporting

multiple harvests and a large dense population. The complicated irrigation system required a group of specialists who ran the system, who in turn became powerful leaders of the state.

In the Mode of Production theory, Eric Robert Wolf, in “Europe and the People Without History,” classified historical cultures into three basic modes of production: *kin-ordered*, *tributary*, and *capitalist*. Kin-ordered relates band and tribal societies or stateless societies. In tributary modes of production, the direct producers possess the means of production. The elite expropriate the surplus product by political or other types of non-economic means. He states that all pre-capitalist states were tributary. *Asiatic* is an example of a strong (centralized) tributary state, while *feudal* is a weaker (decentralized) one; these two replace one another over time. Europe, from the 16th through the 18th centuries, was not capitalist but a mercantile tributary (centralized) state. Capitalism emerged in England in the late 18th century. The capitalist enlisted labor under capitalism through the buying of labor power, leaving the workers with nothing left to sell but this labor power. Liberal political revolution, the industrial revolution, and free trade came together in England partly because of its unique history and its geography. England then became the homeland of capitalism, which divided the world to meet the interests of the British capitalist.

Political anthropology is a sub-specialization within cultural anthropology. Like political sociology, it is a study of how political power is used within a larger social and cultural context. Also, like political sociology, it examines how political cultures and the political institutions change historically. Political anthropology adds a cross-cultural comparison to understand how widely different cultures have generally dissimilar political cultures and political institutions.

POLITICAL ECONOMY

The field of political economy is defined by a set of questions surrounding economic modes of production and their subsequent interactions with both the social and political realm. As such, its research mandate is among the broadest in the social sciences. It impacts questions not just in the disciplines of economics and political science, but in anthropology, sociology, history, geography, and the environmental sciences as well. In their widely read introduction to the topic Balaam and Veseth declare:

International political economy is both the past and future of the social sciences. It is the past because it represents a return to the origins of the social sciences, before the study of human social behavior became fragmented into the discrete fields of economics, politics, science, sociology, history and philosophy. It is the future because, in today's complex world, most important social problems clearly have an international or multinational aspect that is best understood through an integrated study drawing on a variety of tools and perspectives.

Indeed, until the later half of the 19th century no differentiation was made between the economic and political or social modes of analysis. The term “political economy” first gained widespread acceptance following the publication of James Steuart’s *Inquiry into the Principles of Political Economy* (1767). Historically three main schools of thought have in turn dominated this field of inquiry, and all remain important to this day.

The first modern approach to the topic was advanced by the mercantilist thinkers of the 17th century. The main object of these writers was to defend the national interest by building up economic resources and reserves of precious metals. Neo-mercantilist thought, which sees economic success as an important national power resource, is still present today, and is most closely linked to certain realist writers within the field of political science. Robert Gilpin’s “power transition theory” (1981), or Stephen Krasner’s “hegemonic stability theory” (1976) represent important examples of this tendency.

In the 18th century mercantilist ideas increasingly gave way to what is now often called classic economic liberalism. This school emerged from the Scottish Enlightenment, with its best-known students being David Hume and Adam Smith, who, in 1776, produced the seminal work, *Wealth of Nations*. Smith argued that, contrary to the claims of the mercantilists, the unregulated functioning of the markets would best promote the welfare of both the individual and the larger national community as a whole. Further, competing individual interests could be harmonized through the “invisible hand” of the market, yielding efficient social outcomes. While Smith was far from disinterested in questions of national power, it is clear that his approach assigns a much more nominal role to the government in the oversight of economic and social life. These essential insights, and the body of theory that has emerged from them, are today most closely associated with the field of economics, and its specific contributions to this multi-disciplinary research program.

The third classic approach to political economy is found in Marxism. Marx advanced his own theory of history, which allowed his students and him to assert that, far from being a basic unit of analysis, markets are, in reality, an artifact of the historic forces of production. Since the ultimate locus of change and progression in his theory of history is economic materialism, Marx was able to deny that society and

the market really existed or functioned as unique, isolated spheres. Rather than free mutual exchange in perfect markets (which the liberal school claimed guaranteed efficient and beneficial outcomes), real economic life was characterized by the use of socially and materially derived power. The harmonization of interests that the classical economist predicted could not emerge, and instead the economy would be characterized by class conflict pitting workers against the capitalist class.

Marxism has traditionally been one of the most important modes for viewing and understanding political economy. The 1960s and 1970s saw a resurgence in Marxist thought as “dependency theorists” in Latin America (Dos Santos) and “world systems theorists in Europe” (Wallerstein) attempted to expand this basic theoretical framework to deal with the shifting vagaries of chronic underdevelopment in the Third World and the expanding role of transnational corporations in the global political arena.

These general approaches are sometimes referred to as “structuralism,” and are often a preferred mode of analysis for sociologists working in the area. It should also be noted that when anthropologists and geographers use the term “political economy” they are frequently referring specifically to these neo-Marxist approaches to underdevelopment and globalization.

Since the division of economics, political science, and history in the late 19th century, the study of political economy (while still a radically interdisciplinary effort) has increasingly been championed and developed within political science departments. The subfield of comparative politics has tended to focus on detailed investigations of patterns of difference between national systems in its attempt to come to terms with many of the basic problems posed by political economy.

Within the subfield of international relations another approach has been developed, often referred to as international political economy (IPE). While there is substantial overlap with the efforts of comparativists, IPE tends to focus more on systemic problems that transcend national and market boundaries, and thus call for broader methods of study, both in terms of the areas of the world that are examined and the methods that are employed. Anthropologists interested in the interaction of international economic and political forces with local social systems may find much of interest in this literature. Likewise,

detailed and specific studies of the impact of global forces on local communities continue to be needed if the political economy research program is to progress.

Soviet Union collapsed with astonishing speed. Some countries are still caught up in an identity crisis.

Legitimacy: People develop the feeling that the regime's rule is rightful and should be obeyed. A system without legitimacy requires massive amounts of coercion to keep it together and functioning.

Penetration: As the government's writ expands through the country, starting usually with the capital city, it encounters resistance, for many people dislike paying taxes to, and obeying the laws of, a distant authority. Local rebellions are crushed and police are brought in to enforce national authority.

Participation: Once the other crises are solved, people start wanting to participate in some way in their nation's governance. There is usually a struggle to expand the electoral franchise. Parties are formed and attempt to control parliament. Mass participation in politics is usually granted only grudgingly by traditional elites, but once it's institutionalized, the country is usually more stable and peaceful. Withholding participatory rights can lead to a buildup of a revolutionary anger.

Distribution: The last great crisis, probably a permanent one, is over the division of the nation's economic pie. Once the masses are participating in politics, their parties (for example, the Labour Party in Britain, the Social Democrats in Germany) demand that government use its considerable powers to distribute wealth and income in a more equitable fashion. In order to fund a welfare state, taxes grow. Better off people generally fight this trend.

This is a “sequential crises” model of political development; in some countries it seems to fit well, in others poorly. Some nations' histories are just too complicated to make the model fit at all.

POLITICAL ORGANIZATIONS

Political scientists have delineated five “crises” that nations seem to undergo, in sequence, in their political development.

Identity: People develop a national identity over and above their tribal, regional, or local identities. Bretons came to think of themselves as French and Bavarians as Germans. We see now that Uzbeks and Latvians never considered themselves “Soviets,” and because of this the

Britain

In Britain, as in most democratic countries, the relationship between people and political parties is complex, a two way street in which both influence the other. The parties project a “party image,” that is, a view of how people regard the party's policies, leaders, and ideology. Conversely, most voters maintain a party identification, a long-term tendency to regard themselves as, for example, “Tory” or “Democrat.” The strategy of intelligent party leadership is to project a party image that will win the loyalty of large numbers

of voters and get them to identify permanently with that party. If successful, the party becomes powerful and enjoys many electoral successes.

Both party image and party identification are reasonably clear in Britain: Most British citizens recognize the philosophies of the three main parties in general terms, and a large portion of British voters identify with a party. The situation is never static, however; the parties constantly change the images they project, while some voters lose their party identification and shift their votes.

For the deeply confirmed Labour or Conservative voters, those whose party identification closely matches the image of their preferred party, there is little doubt as to whom should be elected.

Until recently, most British voters were reliably Labour or Conservative. The element that changes from one election to another, because either their party identification is not strong or their perception of the parties' images shifts or both, is called the "swing" vote. A swing of a few percentage points can determine who will form the next government, for if each constituency shifts a little one way (for example, toward Labour), the Labour candidate will win in many constituencies. Single-member districts often exaggerate percentage trends and turn them into a large majority of seats. A "swing" of only one percentage point nationwide usually translates into a dozen or more parliamentary seats changing hands, sometimes changing the majority in Commons, and therefore, the government.

Germany

In Germany, as in most advanced countries, personality has become more important than ideology in the mind of many voters. With the decline of the *Welanschauung* parties (a view of the world), and the move of most large parties to the center of the political spectrum, the personality of candidates is often what persuades voters. This has long been the case in the United States and is now becoming the European norm as well. Some call it the Americanization of European politics, but it is less a matter of copying than it is reflecting the rise of catchall parties; throughout Europe, election posters now feature the picture of the top party leader, the person who would become prime minister. Although voting may be by party list, citizens know that in choosing a party they are actually electing a prime minister.

German (and British) campaigns are conducted almost as if they were for the direct election of a president, as in the United States and France. Officially there is no "candidate for the chancellor-ship," but in practice the leading figures of the two majority parties are clearly identified as such in the press and in the public mind so that much of the campaign revolves around the personalities of the two leading candidates.

A German candidate for chancellor must project strength and levelheadedness. In a country obsessed with fear of inflation, the candidate's economic background plays a bigger role than in most nations. Two of Germany's postwar chancellors have been economists. The candidate's adherence to democratic rules also plays a role, and Franz Josef Strauss's authoritarian streak contributed to his defeat in the 1980 race.

Personality contributed to the results of the 1990s elections, too. The Christian Liberal coalition had the steady, optimistic image of Helmut Kohl. The Social Liberal coalition candidates of the 1990s came across as radical intellectuals; they needed an attractive moderate like Tony Blair. Much of postwar German politics can be described as parties groping for the right leader to bring them to power in the Bundestag (parliament), and chancellor's office. When they found the right one, such as Adenauer, and Kohl of the Christian Liberal coalition, they stuck with them all the way to electoral success.

Russia

The trouble with Russia is that there are few rules or institutions to regulate and moderate political clashes. Without experience in multiparty competition, a free press, voluntary associations, tolerance, and simple politeness, the new forces freed by the ending of Party control started to play a new game without knowing the rules. Their clashes were bound to be chaotic, and they were made worse by bureaucrats who had every interest in sabotaging the reform process. Fearful of losing their power and comfortable livings, they fought change, trying to reverse it.

Many of the reformers who rallied under Gorbachev and then transferred their loyalties to Yeltsin have resigned or been dismissed from high office. In many respects they hearken back to the Russian Westernizers of the 19th century who wanted to import Western ways nearly wholesale: a market economy, free democracy, and individualistic philosophy. This led them to attempt the economic "shock

therapy” recommended by Harvard economist Jeffrey Sachs, which earlier worked in Bolivia and Poland. The initial stages of such therapy are terribly painful, and Russia’s economy plunged downward.

The term “conservatives” covers a broad swath from moderates to extremists. Conservatives’ common link is their opposition to shock therapy and similar methodologies. Russia may need reforms, some concede, but the reforms must be ours and must be tailored to our conditions. Some old-line party types would go all or much of the way back to a centralized command economy. Like the old Russophiles of the 19th century, they reject Western models and would turn inward, to Russia’s roots; accordingly, they are nationalistic, some rabidly so.

These two general camps are halves of the Russian political spectrum that contain several graduations and combinations. The extreme end of the conservative side is sometimes called the “red brown” coalition, a combination of old Party supporters plus extreme nationalists. (Brown, from Hitler’s brown-shirted Storm Troopers, connotes fascist.) Zhirinovskiy headed the largest party in this movement, but former General Lebed is seen as its likeliest leader.

More moderate conservatives cluster around Zyuganov’s Communist party.

Under the label “centrist,” another group seeks a middle ground of moderate reforms cushioned by continued state subsidies and ownership. The “Our Home Is Russia” party of Yeltsin’s prime minister,

Chernomyrdin, and, indeed, Yeltsin himself are described by some as centrists, cautious reformers. Thoroughgoing reformers, such as Gaidar and his Democratic Choice party, are a weak force in parliament, and no longer a part of Yeltsin’s government. Russia’s parties come and go quickly, splitting, combining, and changing names, but the main distinction to look for is between those who want reform and those who do not.

China

Following the end of the Maoist reign, a new conflict appeared in Chinese politics, a split between liberal and conservative forces, similar to what the Soviets went through before their system collapsed. The Chinese moderates who opposed the extremism of the Cultural Revolution wanted to essentially go back to their preupheaval society. They earned the nickname the “17-years-before people,” because they thought the 17-year period (1949–1966) before the Cultural Revolution had been good. These tended to be older people, with secure positions in the party, army, and bureaucracy, very much like Soviet conservatives. They wanted socialism on the Soviet model, with centralized control over the economy, politics, and cultural life.

Opposed to the moderates were the liberalizers, usually younger people, who saw the unfairness and inefficiency of central control. They pointed to the amazing growth in output that came with the introduction of private and cooperative enterprises, like in the Special Economic Zones, where industrial growth set world records.

The Chinese conservatives, just like their old Soviet counterparts, feared that such a system would no longer be Communist and, even worse, that their jobs would be scrapped.

This split caused Deng Xiaoping much grief. He was prepared to liberalize cautiously, hoping to confine it to the economic sector, but demands came

bubbling up to go farther and faster. In the spring of 1989, tens of thousands of Chinese university students staged giant protests and hunger strikes in favor of democracy. Deng fired his hand-picked and liberal-minded successor, Zhao Ziyang, and had the PLA execute the students in Tienanmen Square. Several hundred died, and approximately 10,000 were imprisoned. A chill settled over Chinese life. Conservatives also launched anti-Western campaigns. The conservatives had one serious drawback: many were elderly. Time seemed to be on the side of the liberalizers, but not without rear-guard conservative actions.

Brazil

Politics in Brazil have been and continue to be largely a game for elites: big landowners, bankers, and industrialists, top bureaucrats, and military people. The stakes of the game are political power and the patronage jobs that come with it. The rules of the game are that none of the players gets seriously hurt or threatened and that nobody mobilizes the Brazilian masses in an angry way, for that would destroy the game's fragile balance and hurt them all. Accordingly, Vargas, himself a wealthy rancher, was an acceptable player when he supported fair coffee prices for the growers, but when he started to mobilize poor Brazilians he had to be ousted. Kubitschek was a good player who looked after his elite friends and deflected potential discontent with his grandiose plans to open Brazil's interior. Goulart, also a wealthy rancher, was a very bad player: He threatened all the elites and mobilized the masses at a furious rate. Lula (the current President), then an anti-elite labor-union radical, mobilized Brazil's poverty-stricken masses in a way that frightened most of Brazil's elites and increased the chances of a coup.

Brazil's entire political history has been the same elite game: Dom Pedro with his fazendeiro friends, the Old Republic with its Paulista-Mineiro alternation, and the military technocracy with its industrial and bureaucratic clientele. Since Vargas, however, the political mobilization of the masses has been a recurring threat to the game. Periodically, a politician who doesn't like the elite's fixed rules is tempted to reach out to Brazil's masses, both to secure his own power and to help the downtrodden. Seeing the threat, Brazil's elites, through the military, remove it and try to demobilize the masses. Mobilization and demobilization can be seen as cyclical.

South Africa

South Africa's party system is more complicated than most European party systems. In South Africa, there exists both a left-to-right axis and a black-and-non-black axis as well.

The areas where black and non-black parties touch (for example, between Inkatha and the Conservatives) enables dialogue, although not necessarily agreement. Between the Conservatives and PAC, or between the ANC and the AWB, a dialogue is impossible. The crucial area is where the parties are able to conduct a dialogue between them.

South Africa's emerging party system does not look promising. First, no party currently links Africans and non-blacks in a serious way. Ironically, only the Nationalist party appears to cut across the color line, with its white, black, and Indian supporters. Second, the black political spectrum is further left than the non-black spectrum, making a policy consensus difficult. Third, both the ANC and the Nationalists face "bilateral opposition," with forces tugging them both leftward and rightward. The ANC has Inkatha on its right and PAC on its left. The small Communist party is not, in fact, the most-left element working within the ANC, but is actually rather moderate in its views. The Nationalists have the Democrats on their left and the Conservatives on their right. Both of the two large parties could be pulled apart.

The Nationalist party system could collapse. Its salvation may depend upon the emergence of a large, moderate multiracial party; a decrease in the number of parties; and a weakening of both black and white extremist parties.

For over 5 decades, constructive dialogue between South Africa's blacks and whites did not exist. The regime simply governed by coercion and repression. Avenues of legal protest were systematically closed off; black and brown protests were automatically illegal and brutally stopped by the police. It was a virtual prescription for violence: plenty of injustice that could not legally be protested. Riot police used dogs, whips, tear gas, clubs, shotguns, and automatic rifles to disperse crowds of Africans. Secret police and army "hit squads" assassinated dozens of regime opponents.

When some of the worst police state restrictions eased in 1990 and black movements became legal, there were still few constructive interactions between

blacks and whites. Instead of building bridges between the two groups, the Nationalists had deliberately, over the decades, destroyed them. Few whites had contact with Africans outside of a master-servant or boss-employee relationship. For decades there had been no church, club, university, sports association, or political party to serve as a meeting ground. Today, most whites desire a constructive dialogue with blacks. This has proven difficult but is improving. After decades of abuse, many blacks are angry; some are revolutionary. When Nelson Mandela became President of South Africa, the apartheid program ended. Blacks and whites are now forging a reconciliation and working toward a common destiny.

POLITICAL SCIENCE

In its most basic form, political science can be defined as the study of both the institutions that form states and governments, and the political processes that animate them. The project of systematically examining both normative and positive theories of government and social relationships is an ancient one, dating back at least 3,000 years. Plato, Aristotle, Thucydides, and Machiavelli are all claimed as foundation figures within the discipline of political science. Early political thinkers both inquired as to what ideal political

relationships should be (Plato), and sought to describe these relationships as they actually existed (Thucydides and Machiavelli). Both of these lines of questioning can still be found in the discipline today.

While the roots of political inquiry may be old, the modern field is much more recent. Political science as a distinct area of study is only known from the end of the 19th century onwards. Before that the examination of politics was often folded into history. Historian Herbert Baxter Adams (1850–1901) is credited with coining the phrase “political science” in 1880. Adams later founded the *Johns Hopkins Studies in Historical and Political Science* series. However, it was John William Burgess (1844–1931) who was responsible for founding the first school and graduate faculty of political science at Columbia University, also in 1880. Columbia would dominate this field of study throughout the remainder of the 19th and early 20th centuries.

Structure of the Discipline

In the current era the discipline of political science is divided into a number of loosely defined, often overlapping, subfields based primarily on area of inquiry. The most common of these in American departments are: political theory, comparative politics, international politics and American politics. In the last decade many departments have also added “methodologists” who are tasked with developing formal tools that can be used in any of the areas of the discipline. Departments outside of the United States often substitute the study of their own national politics for the “American” field, (which is then often seen as a highly developed branch of comparative politics). Public policy and public administration are often viewed as applied areas of the discipline.

Of the four main fields, American, comparative, and international relations generally adopt a relatively empirical view of the world, and often seek to construct theories based on the logic of scientific inquiry. Americanists tend to be interested in how a certain set of institutions and social processes (democracy) affect political outcomes in the American context. While this is in some senses the most bounded field in the discipline, it is probably also the most richly developed. Comparativists seek to examine different institutional and social structures and ask how those specific differences condition outcomes. Practitioners of international relations are primarily concerned with the principles that order both political and

economic affairs between states and other actors in the international system.

Political theory, in contrast, seeks to construct and interrogate a historical canon of political thought and to more closely investigate ethical and moral questions involving politics, governance, and power. As such, political theory firmly anchors the normative aspect of the discipline. It is also responsible for providing many of the foundational ideas and concepts that are used in other areas' fields.

Methods and Content

One of the most pressing problems facing political scientists is how to circumscribe, or provide some sense of attachment to, their research when the political process is by definition closely connected to so many other social spheres. Several basic approaches to this problem have arisen, all of which are currently seen in the field. The first of these is to start by examining the basic institutions and structures that control governance and ask how these sets of shared rules impact outcomes.

This was the first systematic approach adopted in the field when the German school of *Staatslehre* was imported to the United States by Burgess in the late 19th century. *Staatslehre* was dedicated to studying the differences between state institutions and often adopted a highly legalistic framework for analyzing their impact. However, the institutional criteria for defining the bounds of the field ultimately proved unsuccessful as so much of what goes on in politics is not institutionalized in a way that it is readily accessible to legal theory. As early as 1885 Woodrow Wilson (also a political scientist), in his seminal work *Congressional Government*, argued that in order to understand how real legislative power is wielded we must leave behind "literary" theories of the constitution and instead focus on the emergence of the committee system and how power is actually wielded in the course of the decision-making process.

This then led to the emergence of new ways of conceptualizing the field based on functions, rather than structures. Thus politics were regarded as not so much a set of deterministic legal institutions as an activity in which individuals engaged. In essence, politics became a set of functioning relationships characterized by an exchange of power to allocate both policy and scarce resources. This move allows for a substantial broadening of the field as basic

functional mechanisms, rather than narrowly defined institutional arenas, emerge as key elements of how research areas are selected. The degree of this broadening varies by subfield, but the discipline as a whole has moved well beyond a simple investigation of the structures of states and governments.

Following the ultimate decline of the legalism movement and the trend away from *Staatslehre*, the field moved into an era that is often described as "realism." As Wilson, a proponent of the movement, demonstrated, its main concern was with more accurately capturing the processes by which real political outcomes were achieved. This necessitated a change in methodologies as it was realized that important non-state groups were having a substantial impact on the political process, groups which had previously been overlooked. As new and important social groups were described, specialized areas within the field were created to deal with them.

This paved the way for the behavioral revolution, which affected many fields in the 1950s and 1960s including political science. Increasingly, political scientists decided that it was necessary to describe the behaviors that led to group formation in the first place. This required focusing more attention on individuals to understand the ultimate economic, social, and psychological motivations that contributed to their behavior. Methodological innovation, including an increased formalism, both in terms of an acceptance of the scientific method as a guide for inquiry, and the reliance on formal empirical techniques, characterized much of the work completed in this movement.

Behavioralism became increasingly vocal and skeptical in its criticisms of the older descriptive research tools. Several specific research areas within the discipline (especially American politics and some areas of international relations) have continued to develop this more formalized and empirical approach. Political theory and comparative politics, while still profoundly impacted by the behaviorist revolution, were not as fully penetrated.

This new approach was scrutinized in the early 1970s as a number of criticisms were launched. The most widely debated of these was a movement to bring the state, as a distinct actor with unique interests, back into the investigation of the political process. Second, while behavioralism offered a number of systematic accounts for how a certain set of values or attributes would impact outcomes, it was never concerned with the more basic issue of how

those values were generated in the first place. Last, despite its formal rigor, the research program failed to generate any substantial new, non-trivial, findings that could lead to reliably predictive results.

More recently, rational choice theory has sought to reintroduce formal theory to political science by drawing on insights from microeconomics and game theory. Rational choice theory as a research program is also methodologically individualistic and concentrates on how actors choose between alternative options. While certain scholars working within this tradition attempt to account for issues like cultural change, systemic behavior, and value formation, opinion in the field has been mixed as to their success.

While rational choice theory continues to expand in certain areas of the discipline, it too has come under concerted criticism from the more historical, theoretical, and qualitatively minded branches of the field. Again these scholars point to the lack of new insights or predictive hypotheses as evidence of the bankruptcy of the research program. Further, its formal and mathematic nature makes its arguments relatively opaque to those who are not trained in its traditions. A more recent round of challenges has been posed by a diverse group of scholars grounded in critical theory, constructivism, and to a lesser extent postmodern theory. This debate will likely continue.

Political Science and Anthropology

The last 4 decades have seen increased interest in politics among anthropologists, both as their subjects were increasingly impacted by the turbulent events of the 20th century, and as they have concluded that politics, too, can only be understood in terms of symbols and processes embedded in unique social and cultural frameworks. Introductory textbooks on political anthropology appear with some regularity, and the American Anthropological Association has a section dedicated to the subject. Like political science, political anthropology is interested in the structure and functioning of political systems, but is more likely to see the process as being driven by social and cultural factors. The two fields share a related interest in many of the same research questions, including nationalism, development, establishing of social norms, identity politics, fundamentalism, and political violence.

Of course a pervasive interest in many of these same questions predates the 1960s and is deeply rooted in ethnographic, and particularly British,

social anthropological analysis of non-Western societies. An early landmark work that reviews how social anthropologists perceived politics prior to World War II is M. Fortes and E.E. Evans-Pritchard's *African Political Systems* (see especially the introductory essays). Social, economic, and political analysis have been firmly welded together in works such as E.E. Evans-Pritchard's *The Nuer*, E.R. Leach's *Political Systems of Highland Burma*, Fredrik Barth's *Political Leadership among Swat Pathans*, or Max Gluckman's seminal essay "Peace in the Feud." For the field of political science in general, and international relations in particular, an important insight to emerge from many of these works is the detailed study of the emergence of a clear order in social systems that might be characterized as anarchic or acephalous.

While acknowledging the essential insight of political anthropology that politics is also a cultural system, political scientists can still make substantial contributions to these research efforts, both in terms of basic theorizing about nature and effects of power exchanges, and by laying out a more global overview of large-scale events and trends in which individual, intensive, studies can be placed and contextualized. Much room exists for interdisciplinary cooperation in each of the topics outlined above, and it is clear that both political science and political anthropology could benefit from increased dialogue and collaboration.

POLYANDRY

Anthropologists have long recognized that marriage, while widely variable in meaning and form, is cross-cultural. One way that marriage varies pertains to the cultural norms dictating the appropriate number of spouses in the marriage. Monogamy is a marriage pattern where a person may only have a single spouse at a time. Polygamy is a marriage pattern that allows for multiple spouses. Polygamy comes in two main forms, polygyny and polyandry. In polygynous marriages a man is married to more than one woman at the same time. Polyandrous marriages, which occur in fewer than 5% of societies, involve the marriage of one woman concurrently to several men. Polyandry is the rarest form of marriage, having generally been found only in areas of Nepal, Tibet, India, and Sri Lanka. Each of the groups that practice polyandry differs somewhat regarding the relationship of the husbands to one another, paternity classifications, and socio-economic benefits of the marriage.

In some polyandrous societies, as with the Sinhalese of Sri Lanka, a woman marries men who are unrelated to each other. However, the most common form of polyandry, known as fraternal polyandry, involves the marriage of a woman to two or more brothers. For example, many ethnic Tibetans and the Toda of southern India have wedding ceremonies for a woman and the oldest of a group of brothers, but all of the brothers, even those not yet born, will be considered married to the bride. All will live together to form a family unit.

Another important consideration is sexual access to the wife and recognition of resulting paternity. Most ethnic Tibetans in Tibet and Nepal share sexual access to the wife. Jealousy seems diminished due to solidarity of the brothers. For the Tibetan Ladog people of Nepal, for example, equality of sexual and procreative rights of all brothers is stressed. For the Tibetan

Gyaling people of Nepal, the elder brother is the primary husband and father, and the wife is only obliged to have sex with him. While she, nonetheless, typically engages in sexual relationships with the other brothers, they are not formally recognized as the genitors of any of their children. In contrast, for the Sinhalese of Sri Lanka, while the first husband remains the principal husband, all brothers share the status of father equally, regardless of actual paternity. For the Toda pastoralists of India, the oldest brother claims paternity rights of all children but shares social fatherhood, and associated rights and obligations, to the children.

We may ask what purpose such a rare form of marriage serves. It seems likely that polyandry prevents the division of scarce resources and land while limiting population growth. Successive generations of brothers will hold the land in common, taking a single wife, rather than dividing the land among several new nuclear families. The political and economic position of the household increases as the resources are concentrated and husbands can specialize in diverse forms of economic production (for example, herding, agriculture, and trade) or combine their efforts at a single form.

The future of polyandry is uncertain. A sharp decline of this marital practice has followed modernization and participation in a global economy. As men increasingly work for cash wages, it seems no longer practical to share resources, land, and a wife.

POLYGAMY

Polygamy allows marriage to more than one person at the same time. The practice of polygamy, or plural marriage, includes polygyny and polyandry. Polygyny allows men to marry more than one woman simultaneously. It is much more common than polyandry, which allows women to take multiple husbands. Polyandry is practiced in only a few cultural groups in Nepal, India, and Tibet.

Polygamy appears once to have been widely practiced, but is less common today, yet it is practiced still in some Muslim countries and parts of Africa. In most of the world's contemporary societies, especially where divorce is common and easy to achieve, polygamy is illegal. Although some cultures legally allow polygyny, most North Americans practice serial monogamy where one may have more than one spouse in a lifetime, but never more than one legal spouse at a time. In polygynous societies, such as the Mormon Latter Day Saints or Arabic-speaking Muslim societies, polygyny is indicative of a man's wealth or heightened social status.

Jealousy is a serious threat to the polygynous lifestyle. In sororal polygyny, sisters become cowives because society believes that since they have grown up together, sororal cowives will get along and cooperate better. In societies where the cowives are nonsororal, cowives often establish their own living quarters or households. Additionally, customs which include clearly defined economic, sexual, and familial rights also help reduce jealous feelings. For example, senior wives most commonly maintain special prestige in the polygynous family.

Polygyny was advantageous in societies where pregnancy dictated sexual abstinence. Where postpartum sex taboos existed, new mothers were required to abstain until the child was weaned from the mother's breast. Polygyny was also seen in cultures with an abundance of marriageable women. For example, in postwar societies where many men have died in battle, excess populations of women remain who seek husbands. Other times, men simply choose to marry later in life, again leaving an abundance of women available for marriage.

The other form of polygamy is polyandry. This much less prevalent practice allows women to have multiple husbands. If the cohusbands are brothers, it is called fraternal polyandry. When a woman becomes

the wife of some or all the brothers in a family, the biological paternity of her children are of no particular concern. For example, Tibetans who practice fraternal polyandry do not attempt to indicate any one brother as a biological father. All children are treated the same, and they consider all the cohusbands to be "father."

The reasons that a society practices polyandry are similar to those for polygyny. In some societies, there may have been a shortage of women, which may be linked to female infanticide. Polyandry might also be a response to severely limited resources. For example, to avoid the division of a family farm, brothers will share a wife and preserve the family farm. Polyandry also helps minimize population growth so that standard of living in a polyandrous family would be better than in a non-polyandrous family, or in a family run by an unmarried woman.

POLYGAMY

Polygyny is defined as marriage between one man and two or more wives concurrently. It is one form of polygamy, the marriage of a male or female to two or more spouses concurrently. It contrasts with polyandry, the marriage of a woman to two or more husbands at the same time, which is rare, and with monogamy, the marriage of a man or woman to just one spouse. Serial monogamy is the marriage of a person to two or more spouses in sequence, and can have consequences not unlike those of polygamy.

The concept of polygyny presupposes the universal applicability of the category of “marriage,” which is not in fact a straightforward matter; during the period when anthropologists were trying to agree on the definition of terms of art, it proved difficult to arrive at criteria for marriage that were universally, or even very generally applicable. Consequently, what one anthropologist describes as polygyny another may describe as concubinage. Polygyny entails inequalities in the ability of men to reproduce sexually, but the political and economic consequences of polygyny vary greatly with the bases of social organization.

The Distribution of Polygyny

Polygyny has been widely distributed in human societies through prehistory and recorded history. Ireänus Eibl-Eibesfeldt found that it occurred in 83.5% of a large sample of modern societies, although monogamous unions were 2.5 times more frequent than polygynous unions. Its occurrence has been reported in many recent and contemporary hunter-gatherer and horticultural societies, in precolonial South America, Africa, Polynesia, and Australia, for example. Polygyny was practiced in ancient Hebrew society, and with the exception of certain liberal Islamic movements, is accepted in Islamic societies. It was not officially permitted, however, in ancient Greece and Rome, or in Christian societies, with the exception of early Mormonism.

Perspectives From Sociobiology and Evolutionary Psychology

Sociobiologists and evolutionary psychologists have sought to explain the incidence of polygyny in terms of natural selection. Trivers’s theory of sexual selection and parental investment has been influential. Sociobiologists have explained the widespread institution of polygyny in terms of the differences in male and female reproductive strategies. Pregnancy, it has been argued, involves a much greater investment than male insemination. Men have evolved a desire for sexual access to a large number of women and will compete for access to women, whereas natural selection predisposes women to assess men as potential providers, and for the quality of their genes, as indicated by various markers such as symmetry.

Sexual strategies theory attempts to explain why men tend to adopt short-term mating tactics to a greater extent than women, but recent studies emphasize that both men and women have evolved mixed strategies, and that strategies are conditional in particular circumstances. Depending on environmental conditions, women ought to make a trade-off between male genetic quality and parental investment. For example, with latitude and geographical regions held constant it has been shown that polygyny is more common in societies where pathogens are more prevalent. This has been explained as resulting from women’s favoring indicators of good genes (and hence, resistance to pathogens) as against indicators of exclusive parental investment. Polygyny has also been found to be more prevalent where women have more control over resources. This has been explained by their decreased dependence on male parental investment.

Polygyny in Evolution

Biologists use the term “polygyny” to indicate differences in access to mates, whether or not associated among humans with the institution of marriage. DNA studies have found that lineages associated with the Y-chromosome are fewer than lineages associated with mitochondrial DNA, suggesting that until recently a small proportion of men contributed a large fraction of the Y-chromosome pool at every generation. Dupanloup and colleagues have argued that humans have been “polygynous” through most of their history, but the number of breeding males may have increased and the variance of their reproductive success may have decreased through a recent shift from (institutional) polygyny to monogamy.

Polygyny in Egalitarian Societies

In relatively egalitarian societies polygyny is technically possible where there is an unequal sex ratio, due perhaps to warfare, or where men marry later than women. The latter is the condition that prevailed among Australian Aboriginal people such as the Yolngu and the Yanomamö of the Orinoco basin.

In assertively egalitarian societies such as the G/wi people of the Kalahari Desert, where marriage is by mutual consent, but subject to parental approval, polygyny occurs by mutual consent and is uncommon. In Australian Aboriginal societies polygyny was highly institutionalized, and associated with systems

of marriage bestowal (including infant bestowal) in which marriage choices were limited by kinship, and arranged between potential husband and wife's kin. A female was first bestowed as an infant, or even before her birth, but usually took up residence with the husband around puberty. Marriage was an exchange either in kind (as in brother-sister exchange) or for a prolonged series of gifts and services. Combined with bestowal, leviratic marriage increased the possibility of polygynous marriage. Polygyny in most regions reached levels of two to three women among some older men, but reached very high levels in some regions in the north of the continent.

Polygyny in these societies provided a route to power and influence. Combined with patrilineal groups it was a strategy for increasing group size and political support, and spreading alliances. In some pastoral societies, such as the Turkana, the requirement for bride wealth, together with the control of stock by older men, delayed the marriages of younger men, and was associated with an age grade of bachelor warriors. In other pastoral societies such as the Samburu, an age-set system together with elaborate initiation rites delayed young men's marriages.

Polygyny in Hierarchical Societies

In the hunter-gatherer societies of the Northwest Coast of North America, which were unusual among such societies in having marked inequalities of status, wealth, and power, polygynous marriage was undertaken to establish alliances between families, because it increased household size and labor power, and because it enhanced the ability of high-ranking heads of households to organize potlatch exchanges, and increased the size and competitive advantage of the descent group.

Polygyny was also a feature of African farming chiefdoms, where marriage was associated with bride wealth in the form of cattle and other stock, as well as money. For example, among the Kgatla of what is now Botswana in southern Africa, most commoner men in the precolonial past had only one wife at a time, sometimes two, and rarely three or four. Households with four or more wives were found among members of the royal family or other prominent or wealthy individuals. Chief Kgagamanye, who was chief of the Kgatla from 1848–1875, had 46 wives. Comaroff found that Tswana men had later substituted serial monogamy for polygyny to make strategic alliances.

Turning to an example of a state system, some authors have depicted concubinage in China as polygyny. Patricia Ebrey argues, however, that in traditional China it was illegal and socially disreputable for a man to have more than one wife at a time, but he could have as many concubines as he could afford. During the Song dynasty, concubines, like servants, were most common in wealthy families. The status of concubines differed from that of wives in that no wedding ceremony was prescribed, there was a market for concubines, and they were ranked lower than wives. Rules of incest and exogamy applied to concubines, however, and children of concubines had the same status as children of wives. In the Qing dynasty it became permissible to promote a concubine to a wife under certain conditions.

POLYNESIANS

Polynesia (“many islands”) is one of the three major cultural areas or regions in the Pacific Ocean, the others being Micronesia (“small islands”) and Melanesia (dark or “black islands”). It was Dumont d’Urville who first subdivided Oceanic peoples into these groups based primarily on cultural traits, but these regions also have geographical boundaries, some of which overlap culturally, biologically, and linguistically.

Polynesian societies are generally found within the “Polynesian Triangle” whose points are New Zealand,

Source: © Peter Guttman/CORBIS.

Hawai'i, and Easter Island (Rapa Nui); however, this is not a clear distinction: Numerous societies that speak Polynesian languages or have similar cultural traits are found west of the triangle in Melanesia and Micronesia and are known as Polynesian Outliers. These outliers include Tikopia, Anuta, Nukuoro, and Kapingamarangi, among others.

Lapita, the First Polynesians

Scholars generally agree now that the ancestors of Polynesian people, who made a distinctive type of pottery called Lapita, migrated from insular Melanesia around 3500–3400 B. C. eastward into New Caledonia, Vanuatu, Fiji, Tonga, and Samoa. This ancestral Polynesian society seems to have begun in the latter three of the archipelagoes and eventually moved further eastward into the far corners of the triangle, occupying many of the islands in between.

Archaeologists still debate, however, whether Lapita derives from an indigenous population in Melanesia or represents a completely new group of seafarers who moved southward from Taiwan through the Philippines

on their way into Near Oceania around 2500 B.C. Some archaeologists, such as Patrick Vinton Kirch at the University of California–Berkeley, have been strong proponents of the view that Lapita represented an intrusive development deriving from an expansion of peoples who spoke languages related to the Austronesian family. The earliest pottery from Lapita deposits in the Bismarck Archipelago appears to be related to sites found on islands such as Sulawesi and the Philippines, but the Lapita style of pottery decoration seems to be something unique that may represent a melding of both Austronesian-speaking and Papuan cultures in Near Oceania. Nonetheless, it is clear that Lapita disperses southward and eastward, bringing along a host of new plants and animals as well as a distinctive cultural kit with which to exploit these new island environments.

Archaeology in Polynesia

As archaeological research in Polynesia increased in the 1950s and 1960s, it became clearer to archaeologists such as Jack Golson (Australian National University)

and Roger Green (University of Auckland), that Lapita pottery-producing peoples successfully crossed the nearly 900-kilometer ocean gap between Vanuatu and/or the Solomons into Fiji by 1200–1000 B.C. Other nearby island groups, such as Samoa, were colonized by around 1000 B.C. as evidenced by the spread of early Lapita pottery as well as artifacts made from chert, obsidian, basalt, and other stone. The introduction and cultivation of various plants (including taro) and animals (like the dog, pig, and chicken) also testifies to a new human (and Lapita) presence on these islands.

The continuing social and economic interaction of human groups living in the newer environments of Fiji, Tonga, and Samoa, along with their relative isolation from the Near Oceanic homeland, led to the development of this unique Polynesian culture. Over the course of the first millennium B. C, these cultural traits changed as the highly decorated, dentate-designed pottery characteristic of early Lapita became plainer and thicker. Some tool forms changed in response to the discovery of new stone resources (for example, the adz), while others remained fairly consistent over time (for example, fishing gear). The cultural characteristics that evolved from the first Lapita settlers into ancestral Polynesian cultures included not only plain ware, but adzes made from *Tridacna* (giant clam) shell and basalt; *Conus* shell beads and rings; one-piece *Turbo* shell fishhooks; abraders made from sea urchin spine, coral, or pumice; and a myriad of other tools produced from basalt, obsidian, and various stone types. One can assume that an even wider range of artifacts and other cultural remains made from perishable materials were not preserved in the archaeological record.

Polynesian Seafaring and Colonization

Determining the origin of Polynesians and the method by which they settled islands in the Pacific has been the focus of much research and debate. When Europeans arrived in the Pacific and encountered a mosaic of different cultures, it was evident that many Polynesian groups were fully capable of traveling both long and short distances across the ocean using double-hulled and outrigger canoes, and that they did so freely. Many early explorers commented on how the highly skilled Polynesian seafarers traveled easily over the ocean, and they noted that long-distance round trips between islands were more

an exercise in endurance than an exceptionally difficult navigational exercise. Native groups used the stars for navigation; fixed their location using mental maps of the sea; effectively harnessed the wind; and paid close attention to cloud formations, sea bird behavior, currents, and winds that would reveal an island's location.

Despite these early observations, many of the seafaring and boat-building skills were lost over time, and some scholars began to suggest that Polynesians could have only settled the islands accidentally by going with the prevailing winds and currents from east to west. In the 1930s, Sir Peter Buck (also known as Te Rangi Hiroa) proposed that Polynesians had originated from somewhere in Asia, passing through Micronesia on their way to Samoa and eventually the Society Islands. An alternative and controversial hypothesis was proposed by Thor Heyerdahl in the early 1950s; Heyerdahl suggested that Polynesians had Native American roots, and had instead migrated from the Americas. Although this theory was not taken seriously by most scholars, his famous *Kon-Tiki* voyage from South America into the Pacific using an indigenous form of a Peruvian reed boat indicated that a drift voyage like this could be done. A contrasting theory, but one also based on the idea of drifting, was proposed (also in the 1950s) by Andrew Sharp, who suggested that Polynesians were incapable of purposefully reaching islands by sailing, and that drift voyaging was the norm; in other words, the islands were settled by chance encounter.

These possibilities have been disproven by many lines of evidence. Archaeological, linguistic, and ethnographic research conducted during the last 50 years definitely points to a western migration route. Not only do similarities in artifacts, language, and cultural traits within Polynesia indicate that people purposefully sailed to these islands by going against, across, and down the wind in a general easterly direction, but sophisticated computer models (using historical and modern oceanographic data and experimental voyages) also indicate this to be the case. In 1976 a replica of a Polynesian canoe called *Hokule'a* successfully made the trip between Hawai'i and Tahiti; in 1999 it traveled to Easter Island. Other, similar voyages using experimental craft—many without the help of modern navigation technologies—have crossed the ocean gaps between islands hundreds of kilometers apart.

The ability of Polynesians to settle some of the most remote places on earth is undisputed, and archaeology

is now providing evidence of increased interaction between island groups. Polynesian peoples referred to *Hawaiki*, a place called the “immediate Polynesian homeland,” in the archipelagoes of Tonga and Samoa. Beginning perhaps as early as 200 B.C., but with more credible evidence dating to ca. A. D. 600, Polynesians began venturing out of Tonga-Samoa and migrating eastward into the more remote fringes of the Polynesian triangle. When these migrations occurred is debatable largely because of a lack of reliable radiocarbon chronologies in places like the Marquesas, and lack of field research in the Society and Austral Islands. If the settlement of Fiji-Tonga-Samoa was fairly contemporaneous, but proceeded no further until the first millennium A. D., there would have been what Pacific archaeologists call a long pause of human expansion. Some archaeologists, including Atholl Anderson (Australian National University), have argued that, in order to prove human existence on these islands, artifactual evidence and reliable radiocarbon dates must be found together at primary occupation sites. Others, including Patrick Kirch, instead argue that environmental or “proxy” evidence (such as pollen from plants introduced by humans, increased charcoal counts from forest clearance, or the appearance of non-native animals like the rat or garden snails) are proof enough that humans occupied the landscape without needing to have the artifacts themselves.

If proxy evidence is accepted, the Cook Islands, for example, may have been occupied somewhere between 500 B. C. and A. D. 0. Several archaeological sites in the Marquesas (for example, Hane, Hanatekua) suggest a human presence from 200 B. C. to A. D. 300, but dates from the same stratigraphic layers have been inconsistent, which leaves questions as to the validity of the archipelago’s chronology at this time. Good evidence points to islands such as the Australs, Cooks, Rapa Nui, and Pitcairn as being settled by at least A. D. 900–or 1000; Hawai’i by A. D. 800 (and perhaps earlier ca. A. D. 300); and New Zealand, shortly thereafter, around A. D. 1000.

Despite these chronological issues, some early sites have been excavated in East Polynesia that lend great

Source: Photograph from the Bishop Museum, Honolulu, Hawaii.

insight into human movement across the seascape, traditional navigation and seafaring strategies, human adaptation in increasingly remote (and sometimes partially or completely isolated) environments, settlement patterns, and the rise of sociopolitical complexity.

Polynesian Settlement and Lifeways

Early Polynesian settlements are characterized by smaller villages located on or near coastal areas. Many communities on these islands, not unlike peoples living in other tropical or subtropical island regions, chose to settle along coastlines that were close to freshwater, lagoonal, and/or reef resources. In East Polynesia, dune or beach terrace sites are common during the earlier periods of settlement. Archaeological

evidence suggests that some residential structures were placed on stone pavement, while others had gravel floors. It is thought that the prototypical *marae* temple may have started at or close to this same time.

Early Polynesians were horticulturalists whose Lapita ancestors brought with them over two dozen species of plants, fifteen of which are known from archaeobotanical remains and the remaining from linguistic or other lines of evidence. These cultigens include two major staples for Pacific peoples—taro and yams—as well as coconuts, bananas, breadfruit, tree fruits, and nuts which were transported into the Pacific Islands by Austronesian speakers. Settlers probably had small garden plots and actively implemented a slash-and-burn or swidden strategy of cultivating plants, in which small sections of forest are cut down and burned, thereby clearing the area and providing essential nutrients to the soil. Perennial tree crops were likely scattered in or around the villages, while root and tuber crops like taro were annually cultivated in the forest.

One domestic plant that was extremely important to many islands in East Polynesia (especially Hawai'i, New Zealand, and Easter Island) was the sweet potato, which is indigenous to South America. The issue of whether the sweet potato, as well as the non-native *Lagneria* gourd, was introduced by Polynesians or Europeans was debated for years until research indicated that both were introduced prior to European contact. The fact that the sweet potato was found in places like Easter Island had seemed to support Thor Heyerdahl's westward migration hypothesis; however, it now seems more likely that, given the advanced seafaring capabilities of Polynesians, the Polynesians instead reached South America and brought the sweet potato into the Pacific Islands. As these societies became more technologically proficient at growing these and other crops, intensive forms of agriculture were developed that used large-scale valleys and implemented hillside irrigation systems, sometimes with dire environmental consequences as erosion increased and habitats for native plant and animal populations decreased. One of the largest impacts was to native birds—dozens of which became extinct in Hawai'i and other Pacific Islands after Polynesian arrival.

Although the cultivation of plants was central to Polynesian society, the basic diet was supplemented with foods from the sea. Polynesians exploited a wide range of marine resources including mollusks, crabs

and other shellfish, birds, turtles, and both nearshore and offshore fish. Based on the presence of fish bones found in archaeological sites, it is apparent that the resource-rich, nearshore fisheries were more heavily exploited, although offshore fishing was practiced using watercraft and trolling lure technology, as shown by the artifacts and the fish bones from tuna and other offshore species. Many of these marine resources were used for making tools as well as for food. A plethora of artifacts made from mollusk shell, sea urchin, and bone attest to the importance of rich lagoonal and reef habitats.

The introduction of domesticated animals—namely the pig, the dog, and the chicken—was also a trademark of Polynesians and their ancestors. All three animals originate from Southeast Asia and were brought to the farthest reaches of the Pacific (though not all are found on every island or thought to be equally important within every Polynesian society) as part of the “transported landscape,” representing a major effort by Pacific Islanders to adapt to and transform their environment to suit their needs.

Although marine and introduced foods were critical components in the diets of Polynesians, terrestrial resources were also plentiful. Sea and land bird remains are often found in archaeological sites, as are various species of land crabs. On some islands like Fiji and Tonga, lizards were also exploited for food.

Polynesian Exchange and Social Complexity

Another characteristic of Polynesian societies was the interisland movement and exchange of prized goods and resources that effectively linked communities together. The transport of shell and stone, and the artifacts made from these materials, are a testament to the importance they had to native Pacific Islanders and the prehistoric linkages that long-distance overseas voyaging provided. Through techniques that test the chemical composition of artifacts, it is known, for example, that basalt found at archaeological sites in Mangaia (Cook Islands) originated from the island of Tutuila in American Samoa over 1,600 kilometers away; another study showed that stone for adze-making found in Mo'orea (Society Islands) came from the Marquesas. The remarkable distances covered provide further evidence that sailing was indeed an important skill that was harnessed to purposefully voyage between islands in Polynesia.

As each of the major island groups in Polynesia was settled, the societies developing within became increasingly complex. At the time of European contact, social structure was typified by what has come to be known as chiefdoms, in which societies are hierarchically ranked and led by a chief who inherits the position through kin affiliations (i.e., determined by genealogy). There was great variation in how these chiefdoms were organized, as well as in the size of their populations. Some simpler forms of the chiefdom were found on smaller atolls and had only minor distinctions between social classes, while others, like Hawai'i, were rigidly stratified. Over time these chiefdoms grew in population, became increasingly complex in social and religious behaviors, and made a concentrated shift to agriculture and animal domestication, thereby becoming less focused on smaller game and some marine animals; fishing, however, generally remained an important part of the subsistence.

As populations increased and social hierarchies developed, greater levels of conflict also developed, as is evident from fortifications such as the hilltop villages, or *pa*, in New Zealand, which enclosed residences, storage pits, and other domestic-activity areas in highly defensible positions. The emergence of stratified chiefdoms in Polynesia and the rise of what many have even called an “archaic state” in Hawai'i demonstrate that these island societies and their economies intensified, became more specialized, and transformed their environments to suit the changing needs of a growing population. Continued research will surely lend greater insight into the movement of Polynesians across the vast Pacific Ocean and their magnificent cultural traditions.

Polytheism (from the Greek *polutheos*, “many gods”) denotes a theological system involving a belief in, and worship of, multiple divinities. The term was first popularized in the writings of 18th century European ethnographers as they sought to identify and label the religious beliefs of “primitive” peoples they studied and contrast them to Judeo-Christian monotheism, or the belief in a solitary divinity. Over time, polytheism has been used to refer to various belief systems in which multiple beings are worshipped or propitiated. These may include gods, goddesses, semi-divine beings, good or evil spirits, or the spirits of departed ancestors. Depending upon the tradition, there may be an established and recognized hierarchy of worshipped beings or they may be seen to act independently. They may work in conjunction with one another or occasionally at cross-purposes. There are several significant characteristics typically found in polytheistic traditions, including:

- Each divinity or spirit being is typically believed to have a specific function (such as healing, protection in travel, etc.), to control a particular realm (material or nonmaterial), or to possess a specific power or range of powers. The latter can include forces of nature—such as rain, thunder, a celestial body, the seasons—or it may involve dominion over characteristics of human personality, like love, devotion, compassion, jealousy, revenge, and so forth.

- Each being is generally believed to either possess or adopt a specific human or animal form, aspect of nature, or a combination thereof, as his or her primary vehicle for the purpose of communicating with humans. Thus, a particular animal or natural phenomenon may be viewed as the manifestation of a particular deity, or even as an ancestor spirit. An eagle may signal the presence of a guardian spirit, or an erupting volcano may be seen as the manifestation of an angry goddess. As a result, reverence toward, and worship of, nonanthropomorphic forms, including animals, plant life, objects in nature, and natural forces, are commonplace.

- Singular devotion to one specific divinity is not necessary. Thus, simultaneous propitiation of several deities is common and accepted. In some cases, it is seen as practical and necessary, since different spirits control different realms or powers.

In one manner or another, polytheism is found as a feature of most indigenous religious cultures throughout the world. Of the variety of theistic views that have been grouped into this category, some have also been identified with their own specific terminology. These include henotheism, kathenotheism, and monolatry.

Polytheism is rooted in a desire to perceive, contact, and influence unseen powers and forces that affect human existence. It can be found among the earliest religious cultures of the world, in both the East and the West. Various ancient mythological records and tales reveal beliefs in spirit beings that were propitiated, worshipped, and/or feared. These divinities often existed at the center of the cosmological worldviews of the cultures in which they were found. Prayers, rituals, and offerings to them were seen as fundamental to the maintenance of the known world of the believers. Catastrophes were often viewed as the results of angered spirits. Thus, regular appeasement of such divinities has also been integral in many cultures.

The powers possessed by, or the responsibilities of, the divinities may be inherent, such as in the case of a Sun goddess or storm god, or they may be assigned to them by a higher divinity. Over time, the hierarchy of divinities in various cultures can change, with some beings either falling into disfavor or coming to be seen as powerless, while others rise in prominence and power. Thus, the hierarchy and composition of a polytheistic tradition is not necessarily static. Moreover, even within a tradition itself, different individuals may give preference or deference to a particular divinity

over another. On occasion, the divinity connected with a ruling individual, family, or clan can come to dominate the attention and affection of a people. This can result in its elevation to the top of the hierarchy, and it also may lead to the banning and rejection of other divinities being worshipped at the time, resulting in a monotheistic view. The early histories of both Judaism and Islam suggest this pattern.

Although monotheism is viewed by most Western-educated people as being a more evolved theological view, this is primarily a Judeo-Christian perspective, although it is integral to Hinduism as well. Thus, polytheism continues to be a persistent and prevalent belief system. Moreover, with the exception of Judaism, Christianity, and Islam, polytheistic beliefs are integral in most of the world's religious cultures and traditions. The reasons for this are several. First, human conceptualization of divinity typically endows it with human-like characteristics, in both form and function. Images tend to be anthropomorphic and typically endowed with personality traits ranging from loving and compassionate to jealous and revengeful. In this manner, humans tend to conceive of the divine in their own image and likeness. Most of us experience power, knowledge, and authority as being possessed by many, not one. Whether it be in family, village, community, or nation, power tends to be in the hands of various individuals, and each tends to have a specific power and function. Within such a system, there can be various avenues to gaining assistance from one or more of those who possess these powers. Polytheism reflects this world experience in formulating its depiction of, and approach to, the realm of the divine.

Conversely, if one looks at the monotheistic concept of a solitary omnipotent divinity and at social and political systems in which ultimate power is in the hands of a single being, one typically finds absolute patriarchies, monarchies, and dictatorships. While such systems may be comforting to some, a solitary all-powerful ruler tends to be viewed as more distant from the individual and less available to provide personalized and individual assistance. Moreover, if supplicants unsuccessfully seek assistance from a singular authority, they remain helpless. Thus, the vast majority of individuals in such systems tend to remain weak and powerless. Alternatively, if there are a variety of beings to whom one can seek aid and comfort, the opportunity for success is greater.

Theologically, then, a multiplicity of deities to propitiate can provide comfort in the belief that if one

is not successful in acquiring the aid of a particular divinity, then that person can seek out the assistance of another deity. As a result, it tends to be emotionally and psychologically more assuring to have a variety of possible divine beings to which one can appeal for help. The manifestation of this can be seen in the belief found in many traditions of individuals or families having a special connection with a particular spirit. Examples of this include the Hawaiian concept of *aumakua*, the Hindu concept of *ishtadev*, and even the Christian concept of saints and guardian angels.

Polytheism, therefore, mirrors the common human experience of family, village, and state. It is frequently found in cultures with a clearly stratified social and/or political hierarchy, in which power is held in the hands of different individuals, based on their position within the hierarchy. Different divinities, like different bureaucrats, have different powers. One then approaches and propitiates the being with the requisite power to fulfill the needs or desires of the supplicant. Further, one can focus on a divinity that appeals to the personality of the supplicant. In many ways, then, polytheism is a more pragmatic theological view than is monotheism.

field research during the last fifty years has clearly demonstrated that these apes are closer to the human species than Thomas Huxley, Ernst Haeckel, or even Charles Darwin had anticipated in the nineteenth century. Today, scientific evidence, ranging from biochemistry and genetics to morphology and psychology, confirms those striking similarities between these wild pongids and the human species in terms of organic evolution.

The wild orangutan or “man of the woods” (*Pongo pygmaeus*) is the only great ape of Asia; like the two lesser apes or hylobates (gibbon and siamang), this elusive pongid now faces extinction. This rare but fascinating red ape of Indonesia is found only on the islands of Borneo and Sumatra. Most orangutans live in the upper tropical rain-forest canopy; adult females and juveniles swing among the vines and creepers of this arboreal world, while huge adult males may leisurely forage on the damp jungle floor below.

The wild mountain gorilla of central East Africa (*Gorilla gorilla beringei*) is the largest of the four great apes. It is an introverted but intelligent and powerful pongid. In remote highlands, scattered groups of gorillas freely roam through the lush, wet forests. A social unit is dominated by the magnificent adult silverback male: Such a mature gorilla may reach a height of six feet and weigh up to 600 pounds. Yet, this gentle giant of the primate world is shy and acts somewhat like a recluse.

The gorilla and chimpanzee (as well as the bonobo) are found in Africa. Their striking similarities to the human animal led Darwin to write that the origin and early evolution of humankind had taken place on the so-called “Dark Continent,” a hypothesis that is now supported by both molecular and paleontological evidence. The common chimpanzee (*Pan troglodytes*) is the most curious, intelligent, and extroverted of the four pongids inhabiting the earth today. In the forests and on the woodlands, the African chimpanzees generally exhibit a free-ranging and harmonious existence. Whether in the trees or on the ground, small groups of these apes spend much time searching for food when not playing, grooming, or merely resting in their nests.

The bonobo (*Pan paniscus*) also inhabits Central Africa, but it has remained elusive to anthropologists until the last twenty years. Both in terms of biology and behavior, it remarkably resembles the human species. Unfortunately, this pongid is also an endangered species threatened with extinction.

The pongids are the four great apes: orangutan, gorilla, chimpanzee, and bonobo. Rigorous primate-behavior

Source: © Lynn Kilgore.

Each of the four great apes has no tail, and is both larger and more intelligent than any monkey. The pongid adult dental formula is 2–1–2–3 (also shared by all of the Old World monkeys and humankind). With arms longer than their legs, these apes brachiate through the trees but usually take a quadruped position when terrestrial. Their thumbs and big toes, both opposable, are favorable adaptations for an arboreal life. However, because of their large size, adult great apes spend considerable time on the ground during the day.

Today, these four wild pongids need to be both saved by and protected from the human species, the most dangerous animal of all. To do so, since the middle of the twentieth century, there has been a concerted effort by primatologists to study the great apes in their natural habitats. Such close-range, long-term pongid research supplements those scientific findings as a result of research in laboratories and zoos.

The Orangutan

In prehistoric times, giant orangutans probably inhabited much of Southeast Asia (the hominoid fossils *Ramapithecus* and *Gigantopithecus* are now considered to be ancestral to this red ape). Today, the orangutan is the largest of the three Asian apes but it is restricted to the dense tropical jungles on the islands of Borneo and Sumatra. In the nineteenth century, the naturalist and evolutionist Alfred Russel Wallace spent several years investigating the flora and fauna of Indonesia. In his 1869 book *The Malay*

Archipelago, dedicated to Charles Darwin, Wallace related his encounters with the wild orangutan in the swampy dense forests of Borneo. It is now very disconcerting to read how casually this biologist hunted and killed this very rare pongid in order to obtain specimens for scientific study; nevertheless, Wallace was one of the first naturalists to observe the orangutan's general habits in its natural environment. His report includes physical descriptions of this ape as well as information on its diet, nest-building activity, and arboreal locomotion. Apparently, the orangutan's only past enemies were the leopard, the cobra, the python, and the crocodile;

yet, it is now an endangered species because of the encroachment of human civilization, with the resultant destruction of its habitat and disruption of its activity.

In the twentieth century, zoologist John MacKinnon presented a popular account of his three-year behavior study of the elusive orangutan in both Borneo and Sumatra. In his 1974 book, *In Search of the Red Ape*, MacKinnon gives a vivid picture of this wild pongid's general environment: the endless and inhospitable green jungles of these two islands in which only deep grunts, smacking lips, and crashing branches betray the presence of the shy orangutan. He describes this ape's typical day of feeding, traveling leisurely, and resting in tree nests.

Since 1971, anthropologist Biruté Mary F. Galdikas has rigorously undertaken the first intensive, long-range study of the wild orangutan (*Pongo pygmaeus*) of interior Borneo in its own environment. The late anthropologist Louis S.B. Leakey had inspired her to study this red ape of Indonesia, a project never before attempted by a female scientist. This “man of the woods” is the rarest and least social of the four great apes. Its natural habitat is now restricted to diminishing forests on the islands of Borneo and Sumatra. At present, there are fewer than 4,000 free-ranging orangutans existing in their own ecological niche. Operating from three research campsites within the lowland jungle of the Tanjung Puting Nature Reserve (Indonesian Borneo), Galdikas has devoted herself to two major objectives: the rehabilitation of orphaned orangutans and the ethological study of this great ape in its own environment.

Young, orphaned orangutans usually die from neglect, disease, or malnutrition. At her remote rehabilitation center in Kalimantan, Galdikas prepares these tame animals so that they may eventually adjust to the wild woods. After camp life, the successfully rehabilitated juveniles are returned to their natural habitat to be free and magnificent in the trees. Hopefully, this undertaking will help to increase the number of wild orangutans in their own environment.

The wild orangutan is now an endangered species for two major reasons: Hunters needlessly slaughter many adult pongids in order to obtain infants and juveniles for the “black market” sale to zoos, circuses, museums, or individuals (illegally held apes are confiscated), while farmers continue to destroy this pongid’s natural habitat by cutting timber and clearing cropland, thereby depriving the red ape of forest area, food supply, natural protection, and normal social activity (including sexual behavior). Obviously, there is an urgent need to understand and appreciate the wild orangutan if this unique primate is to be protected from human encroachment and saved from imminent extinction.

Since 1974, Galdikas has followed an adult male orangutan through the Borneo jungle to observe his behavior in the wild. This task has required her venturing through swamps with leeches, mosquitoes, crocodiles, and poisonous snakes. She discovered that this large ape spends much of its time walking on the ground. However, most orangutans are generally arboreal; they move slowly and deliberately through the trees by using their hook-like hands and prehensile feet. The adult orangutan is essentially asocial: There are no problems to be solved in a day-to-day life that demands little cooperation, other than mating and minimal infant care by a mother. Adult males and females are usually solitary or found in loose social organizations. The only temporary social unit is an adult female with her infant or juvenile.

Adult social interaction is infrequent. Two males may engage in combat over a female at mating time; however, there is only sporadic male/female companionship for sexual purposes. Females prefer the larger males as partners in consort relationships. Since orangutans are usually arboreal, there is no group structure or social discipline. They build simple nests in the forest trees or on the jungle ground; during heavy rain, they make a “roof” of leaves. Orangutans rarely groom each other. Their diet is primarily frugivorous and includes buds; shoots; seeds; young

leaves; wild, unripe and ripe fruits; flowers; soft bark; wood pith; honey; termites; birds’ eggs; and insects. In fact, the orangutan uses a stick to extract honey from a tree.

Caged in zoos, the shaggy red ape is lethargic and very prone to both obesity and erotic behavior. It suffers the same diseases humans do, from malaria to the common cold. This pongid may even identify with humans (thereby contributing to problems of sexual reproduction in captivity).

At about the age of 12, an adult male orangutan will exhibit these characteristics: a large-domed head, pronounced cheek pads (flares of tissue), a throat sack (gular pouch), and a beard, as well as at times the making of a long, shrill call. There is marked sexual dimorphism, with the adult male being about twice as large as the adult female. The male may reach a height of nearly five feet, weigh over 200 pounds, and have a cranial capacity of about 200 cc.

The wild orangutan is an independent and gentle creature, living a rather lonely existence and acting viciously only when provoked. Leaving the primeval rain-forest canopy during the day, an adult male spends time on the ground and may even venture out of the tropical jungle. Such an isolated ape may forage for as long as six hours while walking awkwardly for long distances through the rain forest on all fours, and perhaps even nap on the damp, humus-covered floor of the jungle. Although free-ranging, adult females never leave their home area throughout their lives. As there is clearly an urgent need to protect and preserve the wild orangutan, which is sometimes referred to as a “missing link,” the serious research of Galdikas (among others) is a major step to understanding and appreciating this endangered great ape of Borneo and Sumatra.

The Gorilla

The wild gorilla of central East Africa is the largest of the four great apes; this mountain subspecies was discovered in 1847. Until recently, this primate was thought to be a vicious animal of the jungle; in sharp contrast to this view, however, field studies have revealed that this huge pongid is actually shy, gentle and basically introverted, but curious, intelligent, and very powerful.

In prehistoric times, wild gorillas were abundant and ranged freely throughout central Africa. Today this great ape is represented by only three geographically

isolated subspecies: the lowland or valley gorilla of central West Africa (*Gorilla gorilla gorilla*), the highland or mountain gorilla of central East Africa (*Gorilla gorilla beringei*), and a third subspecies also found in central East Africa (*Gorilla gorilla gmveri*). The differences among these three subspecies are minor: the mountain gorilla is larger and has thicker hair (an adaptive advantage), shorter arms, a narrower skull, a longer palate, and does not share its forest with wild chimpanzees.

Now an endangered species, the vanishing wild gorilla needs to be understood and appreciated in order to ensure both its protection and survival in captivity as well as in its natural environment. It is estimated that only about 240 mountain gorillas now inhabit the lush, wet, tropical jungle areas of central East Africa. Their ecological niche is gravely threatened by hunters, farmers, and poachers; thus the desperate plight of this mountain pongid.

George B. Schaller, a zoologist, was the first scientist to seriously study the wild mountain gorillas (*Gorilla gorilla beringei*) in their own habitat. His pioneering, twenty-month research project (1959–1960) remains a classic contribution to primate ethology. He presented his important findings in two books: *The Mountain Gorilla* and *The Year of the Gorilla*.

Gorillas are primarily quadrupedal and terrestrial, living in the humid rain forests of Africa. In his extensive study of the mountain subspecies, Schaller concentrated on the ecology and general behavior of this remarkable great ape. His 466 hours of direct observation were made from the viewing advantage and safety of trees. He was able to watch free-living gorillas wander through the dense jungle, forage on succulent herbs and vines (they prefer young, secondary forest growth), groom and play, defend territory, and build nests in the trees or on the ground. The zoologist observed no tool use, no meat eating, and no drinking of water; furthermore, gorillas do not like to get wet. Both vocalizations and sexual behavior are infrequent. Of particular interest, however, is the wild gorilla's chest-slapping behavior, an elaborate sequence of nine distinct acts to relieve frustration.

Despite his dedicated study of this great ape for nearly two years, Schaller never made physical contact with the mountain gorilla; this incredible feat was first accomplished by a remarkable primatologist, Dian Fossey (to date, the other two gorilla subspecies have not been seriously studied in their own habitats).

In 1967, the late anthropologist Dian Fossey began living among the wild highland gorillas of the Virunga Volcanoes in central East Africa. Her research—camp, Karisoke, is located in the ancient rain forest of Mt. Vasokie; it is a tropical jungle world of fog and mist in Rwanda near Zaire.

Encouraged by the late Louis S.B. Leakey and following in the footsteps of Schaller, Fossey undertook to investigate the mountain gorilla in its natural habitat with only notebook, camera, and binoculars. Her courageous and intensive years of observations between 1967 and 1985 in the ancient rain forests resulted in an invaluable scientific as well as compassionate contribution to the understanding of and appreciation for this giant of the primate world. Like the orangutan, chimpanzee, and bonobo, the free-living mountain gorilla is an endangered species. Because of the ongoing encroachment of human beings with civilization, this largest of the four great apes is now a vanishing animal threatened with extinction.

In 1984, Fossey published *Gorillas in the Mist*, in which she gave a personal account of her thirteen-year study of four family groups of this rare pongid among the dense and remote rain forests of those dormant Virunga Volcanoes in central East Africa (Rwanda, Uganda, and Zaire). She followed gorilla groups on the ground in order to observe them at close range during their leisurely day-long search for food and shelter. Fossey was very successful in establishing a rapport with the mountain gorillas. Habituation required her patiently learning to imitate their feeding methods, general sounds, basic gestures, submissive postures, and vocalizations of contentment. This led to her being gradually accepted by these wild pongids, which are usually timid despite their size and power. Her book focused on various group dynamics and behavioral patterns: social range, kinship bonds, nest building, group structure, play and grooming, sexual habits, ritual displays, inter-group and intra-group interactions, cannibalism, and even infanticide. Fossey also wrote about the gorilla's vegetarian diet, mountainous ecosystem, territoriality, and diseases.

As a result of Fossey's relentless efforts, she was able to examine the uninhibited behavior of mountain gorillas under normal conditions in their natural range. Her close-range, long-term, intimate study of this highland pongid was a rich and rewarding experience for science. Unlike Schaller, and only after

a long period of slow habituation, Fossey was able to actually make physical contact with several of these apes; the first time a scientist has touched this primate in its own habitat.

In the glorious rain forests, this magnificent great ape is primarily a ground-dweller and usually a peaceful vegetarian. Yet a nervous adult gorilla will hoot, mouth a stick or leaf, rise bipedally, thrash branches and vegetation, slap its chest, kick its legs, run sideways, and finally thump the ground with its palms. It may even bluff a roaring "charge" as protective action if necessary, doing so only when provoked (this fierce-looking and very powerful ape will try to avoid physical contact with intruders). In truth, this pongid's alleged savagery toward human beings is grossly exaggerated. However, gorilla brutality does exist. This ape is capable of aggressive behavior and even murder, including infanticide.

A mountain gorilla's staple diet consists of fruit, bark, roots, thistles, nettles, wild celery, blackberry leaves, galium vines, and other such succulents. Primarily folivorous, this ape has never been observed eating meat, insects, or even birds' eggs in its natural environment (the lowland gorilla is both frugivorous and folivorous).

Most gorillas live in small, scattered groups which usually consist of about ten individuals (there are even both peripheral and loner blackbacks as well as silverbacks). These stable social units roam through the rain forests of central West Africa and wander on and below the slopes of the Virunga Volcanoes. A social group is dominated by the adult, alpha silverback male. Other members include a hierarchy of subordinate blackback males, adult females, juveniles, and infants.

The fearsome adult silverback male gorilla is characterized by nuchal and sagittal crests, a prominent supraorbital torus, marked prognathism, long arms and powerful shoulders for modified arboreal brachiation, and a quadrupedal stance on the ground with the weight of the body supported on clenched knuckles and plantigrade feet (the presence of silvery grey hair on his back, rump, and hind legs clearly indicates a dominant adult male). Fossey discovered adult males to be unusually protective and tolerant toward the young; she once saw an old male tickle an infant with a flower, as might a kindly grandfather. Protected by the dense jungle foliage and with the advantage of its huge size, an adult, male mountain gorilla may even live as a loner (apparently the

leopard, buffalo, and elephant are no serious threat to this great ape).

Each gorilla has a unique personality as well as a distinct nose print and voice print. These gorillas communicate by using at least twenty-two distinct sounds.

The gorilla is an intelligent animal; in the rain and bamboo forests of mountainous central East Africa, more fully developed mental capabilities would not have increased its fitness. In the safety of the tropical jungle, there is no need for this ape to tax its brain (this had resulted in an early underestimation of this pongid's true intelligence when compared to the extroverted behavior of the chimpanzee and bonobo). Because of its awesome size as well as brute strength and placid nature, it is extremely difficult for a human being to train and manage the mountain gorilla in captivity.

Until recently, captive gorillas were displayed as prisoners in small, sterile cages which cruelly removed them from their normal biome and essential troop behavior. Fortunately, growing numbers of concerned biologists and anthropologists are becoming involved with the survival of this great ape in captivity. In zoos, the gorilla is prone to fatal pneumonia and tuberculosis; therefore, all artificial environments must be carefully watched and controlled. Unfortunately, it is also very difficult to mate this huge pongid in captivity; gorillas require privacy and conditions similar to their natural habitat for successful sexual activity (in fact, a gorilla may even identify itself with a human being).

The mountain gorilla is in grave danger of extinction. This pongid's precarious existence is threatened by human encroachment and ongoing neglect. Civilization is slowly engulfing the shrinking domain of this magnificent ape. If serious measures are not taken immediately, this unique, giant anthropoid of the natural primate world will soon vanish from the earth forever.

Concerning extinction, several factors are determined by the evolutionary history of a particular primate and its own genetic information, for example, such species-specific factors as: size of the original geographic range, natural habitat requirements (ecosystem), population density limits, body size and weight, and behavioral traits. Other contributing factors include habitat alteration or destruction and human predation (i.e., hunting, collecting, and killing). Of course, humankind still remains the greatest danger to the survival of the wild gorilla in

its own environment (and to the survival of other threatened primates). One alarming point: for the survival of this impressive animal, prompt and strict conservation measures are necessary, or else the impressive mountain gorilla will soon disappear. There is an urgent need for both the short-term preservation and the long-range conservation of this giant ape so that future generations may benefit from understanding and appreciating this remarkable pongid.

The gorilla is a key species in the scientific study of primate evolution, biology, psychology, and behavior. Fossey's pioneering research was both an intimate portrait of and an accurate report about this imperiled mountain pongid, dispelling legends and myths surrounding this majestic rare ape while bringing its plight to the consciousness of both naturalists and general readers. Her steadfast dedication to, and deep concern for, these precarious creatures represented primate ethology at its best.

Ongoing research in Gabon, central West Africa, is providing needed information on the ecology and behavior of both lowland gorillas and chimpanzees (sympatric apes in the lush, tropical rain forest of Lope).

The Chimpanzee

Since 1960, anthropologist Jane Goodall has been studying the wild chimpanzee (*Pan troglodytes schweinfurthi*) in its natural environment. She has lived among chimpanzees in the tropical rain forests and woodlands of central East Africa; her patient, sustained, and courageous efforts for over forty years have resulted in remarkable discoveries about the behavior of this great ape. Goodall had been inspired to observe the wild chimpanzee in its own habitat by Louis S. B. Leakey. Her dedicated and pioneering research is now recognized as a milestone in primate ethology. Her two books, *In the Shadow of Man* and *The Chimpanzees of Gombe: Patterns of Behavior*, are major contributions to the scientific literature on pongid behavior.

Among the primates, as well as in terms of biological evolution, the chimpanzee is closest to the human species. Goodall has studied this wild ape at close range in the Gombe Stream Research Center on the shore of Lake Tanganyika in Tanzania. Established in 1943, this natural park remains a sanctuary for approximately 100 chimpanzees. With only her camera and binoculars, Goodall followed these trusting pongids into their own habitat. This unique, long-term,

scientific study of a wild chimpanzee community yielded incredible new findings of inestimable value about this human-like ape of Africa. As a direct result of her impressive field research, she is now the preeminent authority on this endangered species.

The chimpanzee is found throughout tropical Africa and is both arboreal and terrestrial. When in the trees, it is capable of modified brachiation, but while on the ground it will walk quadrupedally on the knuckles of its hands and on the outsides of its feet. Occasionally, it does stand erect in order to move about in bipedal locomotion for short distances.

Unlike the orangutan and gorilla, the chimpanzee is an extroverted pongid (like the bonobo). In captivity, chimpanzees are easily trained for circuses and zoos. In the wild, they live in open, poorly defined, temporary, and unstable nomadic groups. A shifting band of 60–80 members consists of a hierarchy: adult males with a temporary male leader, young males, females with babies, and females without babies. There is no nuclear family unit; the only temporary bonding relationship is the parental care of an adult female for her infant or juvenile. Play and mutual grooming seem to ensure a state of well-being among the members of this pongid society.

Chimpanzee sexual behavior is grounded in biochemistry. Mating habits are normatively promiscuous, but only when the adult female is in estrus. Presenting and mounting are typical social behavior patterns among the adult males, representing subordinate and dominant actions, respectively.

In nature, chimpanzees live a casual life within constantly shifting groups (these societies meander within a home range). They may even defend their territory against other intruding chimpanzee units.

Chimpanzees build nests and dislike getting wet. Whether living in dense trees or on the jungle ground, these apes apparently fear only large cats (especially the lion and leopard) and the human species. In fact, human civilization is the major threat to this pongid's existence in the wild. Chimpanzees show much individuality, differing in their facial expressions and mannerisms. They are very intelligent and highly emotional; their temperament ranges from violent aggression to gentle playfulness. Actually, one may even speak of chimpanzee personalities.

Chimpanzees communicate and control behavior through a variety of calls as well as by touch, gesture, and cooperative behavior patterns (especially play and grooming). A chimpanzee group is dominated by

the top-ranking or alpha male, and each sex has its own fluctuating dominance hierarchy.

The bulk of chimpanzee food consists of fruits, leaves, and blossoms, as well as seeds, stems, bark, and nuts. Occasionally, this ape will add ants and termites to an otherwise basically frugivorous and vegetarian diet. Goodall's major discovery is that wild chimpanzees make, use, and transport simple tools. They deliberately modify stems, twigs, sticks, or blades of grass for the specific purpose of probing insect mounds at certain times in order to extract and eat ants or termites (thereby challenging our species as the only tool-making animal). They seem to consider such insects as delectable morsels. Chimpanzees also crumple and chew leaves to make a "sponge" for obtaining water from notches in trees or for sopping up the soft brains from inside a monkey's skull cavity. They even use large leaves as containers for carrying water, and also use sticks and stones as weapons. These activities clearly demonstrate intelligent, learned behavior in a social environment. In short, wild chimpanzees have a technology—albeit a very simple one. Wild chimpanzees are not only tool-makers, but also meat-eaters, occasionally adding raw flesh to their general diet. They will hunt, kill, and eat small red colobus, redtail, and blue monkeys (including infant baboons), as well as young bushbucks and young bushpigs.

Goodall was the first primatologist to observe the frenzied "rain dance" ritual of this great ape, a stylized display of apparent nervous behavior. During a thunder-and-lightning storm, excited male chimpanzees stage a unique pattern of activity: They leap to the jungle floor and careen through the grass, then charge downhill while bellowing and brandishing boughs; this activity is followed by the act of slapping the ground or swatting at trees. This activity may last up to thirty minutes. Females and their young are merely arboreal spectators.

Goodall also discovered that wild chimpanzees can display aggressive behavior and extreme brutality; they are capable of murderous violence and primitive warfare. At times, these apes are savage killers and ruthless cannibals. Between 1974 and 1977, she observed the clash between two neighboring chimpanzee groups that resulted in the gradual extermination of the small southern Kahama society by the apes of the northern Kasakela region. It had not been known previously that wild chimpanzees would systematically and deliberately attack and kill one another. Slaughterous

behavior may be grounded in territoriality, as one ape group defends its home range against unwanted intruders. Goodall also witnessed adult chimpanzees killing and eating their infants. Perhaps such primate aggression is biologically inherited, an innate aspect independent of social and environmental forces.

Goodall's pioneering research has resulted in original information on wild chimpanzee vocal communication, sexual activity, social hierarchies, facial expressions, greeting gestures, parental care, nest building, diseases, diet, grooming, and play. In general, chimpanzee behavior bears uncanny similarities to human behavior.

Since the publications of Huxley, Haeckel, and Darwin in the nineteenth century, naturalists have become increasingly convinced that the human species does share a common prehistoric ancestor with both the chimpanzee and the gorilla. Fossil and genetic evidence suggests that a momentous split in primate evolution occurred about five million years ago, resulting in one route leading to the three living apes of Africa and another to the human animal itself.

The anthropologist Adrienne Zihlman argues that the common ancestor shared by the chimpanzee, bonobo, and the human species was probably a hominoid that looked and behaved very much like the contemporary pygmy chimpanzee (*Pan paniscus*), that rare and intriguing great ape of equatorial Africa. If her hypothesis should prove to be true, the pygmy chimpanzee of today represents a living link with our remote evolutionary past.

Chimpanzees are fascinating creatures with advanced brains and complex behavior. They demonstrate mental capacity for foresight, learning, symbolizing, problem-solving, and even self-awareness. As a result of rigorous research in biochemistry and ethology, one fact has been clearly established: The human animal is closer to the chimpanzee and bonobo than to any other living species. Jane Goodall's impressive field work supports this conclusion and contributes to those efforts in preventing the extinction of wild chimpanzees.

The Bonobo

The wild bonobo (*Pan paniscus*) is found only in the forests of the Democratic Republic of the Congo, Central Africa, where about 15,000 members of this species now live. Although known as the pygmy

chimpanzee, this great ape differs from the common chimpanzee. Compared to the chimpanzee, the bonobo has a smaller head, a darker face with tufts of hair on each side, and is taller with a more slender build (narrower shoulders, and legs longer relative to arms). It is a peaceful and gentle pongid.

Bonobos have been scientifically studied only during the last two decades. They are more arboreal than chimpanzees, but less aggressive and less excitable, with violent behavior being very infrequent. Bonobos live in female-dominated, fluid social groups that are headed by an adult alpha female. Their sexual behavior is frequent, promiscuous, and inventive (bonobos literally “make love, not war” in order to reduce tension and resolve conflict).

Bonobos use objects (for example, stones and branches) as tools, stand erect, and walk upright for short distances more often than chimpanzees and gorillas, and they display a range of emotions and activities that suggest an eerie resemblance to how our remote ancestors probably looked and behaved. One bonobo has even figured out, by himself, how to make a simple stone implement like those made by our own remote hominid ancestors in Africa 2.5 million years ago.

Significant bonobo research is being done by Frans B. M. de Waal, whose unique book, *Bonobo: The Forgotten Ape*, which released in 1997, is particularly important to understanding and appreciating this pongid. Ongoing field studies of the wild bonobos by biologists and anthropologists will shed more light on the bio-social origin and evolution of the human species.

The gap between modern humans and the four great apes is very narrow, indeed (demonstrating how remarkable were the original insights of Huxley, Haeckel, and finally Darwin himself). Even so, only the human species is capable of sustained bipedality, using symbolic language as articulate speech (not to mention the complexity of its abstract thoughts and intricate behaviors), and creating an extraordinarily multifaceted socio-cultural milieu in which simple implements are used for the manufacturing of far more complex tools, weapons, and other objects.

If the human species journeys to other planets and beyond, then it will carry with it those indelible bio-social marks of its primate origin and evolution on earth. Even as the future cosmic ape, humankind will always remain akin to the four living pongids on earth.

APE CULTURE

Anthropologists and other scientists have discovered that nonhuman primates convey specific behaviors associated with demonstrating power. Within ape culture, the bonobo and the chimpanzee exhibit opposing approaches to the concept of power. As the least aggressive species within the great ape family, bonobos are rarely interested in displays of power. The bonobo society is matriarchal, and sex replaces aggression as the means of resolving conflicts.

Despite their intense interest in sexual activity, bonobos do not engage in the showy display common to dominant male chimpanzees, which may be consumed with the need to demonstrate power over females and subordinate males.

A male chimpanzee, with hair raised, may display with loud noises and excessive use of force, snatching up and throwing surrounding objects such as trees, rocks, and vegetation. The displaying chimpanzee stands erect, exhibiting fierce facial expressions and may engage in hooting, swaying, slapping, flailing, drumming, raking, or chest beating. In zoos, dominant male chimpanzees tend to be less showy but still impressive. Such chimpanzees stand tall to appear ferocious and may also drag or throw trees and other objects. In captivity, the chimpanzee may run downhill screaming, or may bang and kick the walls of the cage.

The attention-getting behavior of the displaying chimpanzee is generally designed to solidify the male chimpanzee's leadership position within the chimpanzee community. Chimpanzee displays are rarely violent because other males tend to subjugate themselves rather than fight the acknowledged leader. Violence can, however, occur among chimpanzees. At least one case has been reported where a group of male chimpanzees attacked and killed a lone male chimpanzee that was not part of the group. Male chimpanzees have also been known to kill the offspring of unknown female chimpanzees.

Japanese primatologist Toshisada Nishida recently observed what well may be one of the most impressive displays of male chimpanzee behavior. In the Mahale Mountains National Park in Tanzania, Nishida observed a high-ranking male chimpanzee displaying near a riverbed. On a regular basis, the chimpanzee picked up huge rocks, which he then rolled downhill. The thunderous noise cowed and impressed all other male chimpanzees in the group, making it less likely that they would challenge the displaying chimpanzee for dominance.

Unlike the male chimpanzee, the male bonobo may display simply by engaging in a brief run while dragging a branch behind him. Bonobo males are also unlikely to form coalitions of supporters to challenge opposing leaders as chimpanzees do. The bonobo is inclined toward one-on-one interaction. In the chimpanzee community, however, coalitions

frequently result in an entire society waging war against one another until one group gains dominance. During the battle, chimpanzees, like members of opposing political parties, may attempt to convince other members to switch sides. If cajolery does not work, the male chimpanzee may resort to force. When a male chimpanzee concedes dominance to another member of the group, the loser literally grovels in the dust in front of the dominant chimpanzee as the leader engages in a moderate-display exercise.

Anthropologist Jane Goodall discovered a unique form of chimpanzee display among the chimpanzees of the Gombe Game Reserve in Africa. In the Kakombe Valley along the Gombe stream, Goodall witnessed groups of both male and female chimpanzees approaching the waterfall, in what she considered to be awe. Goodall noted that for several minutes, the chimpanzees displayed in a slow, rhythmic motion, sometimes heaving large rocks or branches into the stream. Some chimpanzees swung out over the stream to get a closer look at the waterfall. While display among female chimpanzees is not unheard of, it is rare.

POPPER, KARL (1902–1994)

Karl Popper was one of the greatest political philosophers and philosophers of science of the mid-20th century. Born in Vienna in 1902, he was educated there and allied himself with the political left. Intellectually, he positioned himself in opposition to the “Vienna Circle,” who advocated logical positivism. During the triumph of fascism in the late 1930s, Popper left Europe for New Zealand, and then in 1946 immigrated to England, where he spent the rest of his life, teaching for 23 years at the London School of Economics, ultimately as Professor of Logic and Scientific Method.

Popper's vision of science, published initially in *Logik der Forschung* in Vienna in 1934, and as *The Logic of Scientific Discovery* in 1959, stressed “conjecture and refutation,” to borrow the title of a later book of his. Popper did not believe that ideas in science developed

by inferring from facts to more general understanding. Rather he believed that scientists drew on their insights to make a conjecture, a hypothesis. The next step was not to find all supporting evidence, but to seek any evidence that went counter to the hypothesis, and which, if found, would refute it.

For Popper, the most essential feature of a scientific theory was its refutability. That is, for a theory to be scientific, it has to specify that under certain conditions some things would happen, and—this is the crucial point—other things would not happen. In other words, a scientific theory had to forbid certain results. This quality allows scientific theories to be tested, and supported or refuted by the findings. Popper believed that a theory could never be proven; only its supporting evidence could be increased. However, a theory could be refuted decisively with contradictory evidence.

Here is a simplistic anthropological example: Let us assume that after studying a number of hunting peoples, we hypothesize that “all hunters and gatherers are nomadic.” Once we have defined “hunters and gatherers” and “nomadic,” so that we are clear about what we are talking about, each new case of hunting peoples that we encounter is a test of the hypothesis. Many such peoples are nomadic, and thus support the hypothesis. But once we discover the peoples of the Northwest Coast of North America, peoples who lived by hunting and gathering but who lived in permanent villages and could in no way be considered nomadic, we must conclude that our hypothesis has been refuted and must be considered incorrect.

Popper believed that several of the most popular theories of his day, Marxism and Freudianism, were unscientific, because they were used to explain everything and forbade nothing. That is, whatever happened could somehow be explained: for example, in Marxism, if the working class rebelled, it was seeking to protect its interests; if it did not rebel, it had a “false consciousness.” In Freudianism, an overprotected child was expected to be timid; a bold overprotected child was the result of a “reaction formation” and expected. Thus, theories that purport to explain everything really explain nothing; they are little more than totalistic ideologies.

Popper’s political philosophy followed seamlessly from his philosophy of science. He was in favor of open debate and democracy, and opposed both fascism and communism as closed, totalitarian systems that violently suppressed legitimate disagreement. Popper’s main work in this vein, *The Open Society and Its*

Enemies (1945), offered a major critique of both Plato and Marx. Popper opposed closed societies because they were not susceptible to evidence, and he opposed revolution and radical change, because they were based on general models and did not allow correction of the many complex unintended consequences of change.

Popper’s emphasis on an “open society” that is friendly to debate and diverse views is informed by his conception of evolution as a process of problem solving, set out in his *Objective Knowledge: An Evolutionary Approach*. Once language evolved in humans, environments expanded to three: World I, which is the objective, natural, and material world; World II, the human subjective mental world; and World III, the results of human mental work, including languages, social and moral codes, law, technology, the arts, philosophy, the sciences, education, and related institutions. World III then produces artifacts, such as buildings, settlements, machines, and recordings of cultural knowledge, which exist in World I.

In the first phase of human invention, cultural patterns institutionalized in World III were regarded as immutable and closed to legitimate change. This unchallengeable orthodoxy, commonly justified by religion, limited experimentation and the search for superior solutions. The next great revolution in human culture came with the acceptance of criticism, which, according to Popper was the foundation of science. Thus open societies encouraging criticism are necessary for progress. Popper’s approach to the evolution of society has been taken up in Ernest Gellner’s *Plough, Sword, and Book: The Structure of Human History* (1988).

POPULATION EXPLOSION

The term *population* is commonly used in the realm of statistics. For a statistician, the term refers to a collection of items. Demographers use the term similarly to refer to the collections of persons alive at specified points in time that meet certain criteria. This definition of the term population connotes the specification of various conditions when referring to a population of a given nation including the specific date or year, place, and the types of individuals who are legal residents, or any person who resides within the boundaries of the nation. At a different level of understanding, the term population is also used to mean a different kind of collectivity, one that persists through time even though its members are continuously changing. From this perspective, the collectivity of an aggregate of persons, those who have ever lived, and those who are not yet even born to live, within a boundary of a given nation represent the concept and notion of a population.

Since the second half of the 20th century, and at the advent of the third millennium, the expression “population explosion” has been associated with the state of the unprecedented rate of growth of the number of humans inhabiting the Earth. A high rate of growth that was witnessed during the 19th century in Europe was considered as an opportunity in terms of a larger labor force and a wider market for commerce. A similar rate of population growth toward the end of the 20th century, however, is viewed as problematic with the rise of consciousness of the limits of the benefits of growth. The optimists, however, challenge this view with the notion that population growth, rather than problematic, has been a condition for the economic development humankind has witnessed.

Historical Accounts and Trends

The population size of approximately 300 million has been fairly consistent and stable during the first millennium. Since the middle of the second millennium, however, population began to rise significantly as the result of new developments and inventions, ranging from the printing press and scientific practices all the way up to the Industrial Revolution. By the middle of the 20th century, the world population counted 2.5 billion. Increased yield from harvest, good health

services, transportation, and increased availability of clean drinking water have led to the improvement of life for humankind while also contributing to the growth of its population. The world is growing in its population by more than 76 million people per year. The world population has doubled in the last 40 years, growing from 5 billion to 6 billion in only the last 12 years. Within a range of a century, from 1900 to 2000, the world has witnessed a growth of population from 1.7 billion to an estimated 6 billion. Fertility rate is declining, but so is the death rate. Population decline is a phenomenon of only a smaller percentage of the nations of the world, whereas it is an increasingly alarming social phenomenon in most of the developing world. The poorer regions hold the majority of the Earth’s inhabitants.

The world population, which reached 6 billion in 1999, is projected to approach 9 billion by 2050. And much of the growth in 2050 will be mainly in Africa, Asia, and Latin America. The population of the developed world will remain stable at its present size while even declining in some nations. Thus, in the projected time of 50 years, Sub-Saharan Africa’s share of the world’s population will increase from 10% to 17%. To the contrary, the share of the population in Europe will decline from 13% to 7%. The population of the developed world is outnumbered now 4 to 1 by the population in developing nations. This proportion will change to 7 to 1 in 2050.

Several factors explain the state of the high rate of population growth across the world. The major reasons for the growing rate of population explosion include a high rate of fertility that is above the level required for replacement of generations, low mortality due to the rise of high life expectancy, migration that raises population among some nations, and favorable age distribution in which there is a high ratio of young people, capable of giving birth, to older adults. In particular, growth in the youthful age, a group capable of reproduction, which is referred to as population momentum, would account for more than half of the population boom projected by 2050.

The growth rate of population has been interpreted differently at different periods of time. The interpretation has also varied depending on where the rate of growth is happening. During the 19th century, rapid population growth that took place in Europe and North America was favorably associated with economic prosperity in relation to a larger workforce and expanded market. In the 20th century,

however, the perception about rapid population growth changed as the new phenomenon of population explosion began to take place in Africa, Asia, and Latin America. This latter development brought about a new experience in that high population growth rate took place without the corresponding economic dynamism in the developing world. This is an unintended outcome of the impacts of western influence shared by the developing world. The introduction of health services, instead of creating economic boom, contributed to the fall of the death rate, in turn, leading to an increase in population growth rate in the developing world.

The birth rate that had risen in the first half of the 20th century continued to do so in the 1950s and 1960s. In 1950, a woman gave birth to six children on average in Africa, Asia, and Latin America. Declines of fertility have been witnessed since the late 1960s in many developing countries. From 1990 to 1995, total fertility rate stood at 3.3 children in all developing countries taken together. However, the range is so wide across regions. For instance, the rate of fertility for Sub-Saharan Africa, which includes Ethiopia, is higher, standing at 5.9 compared to the drastic fall for East Asia, which is 1.9.

The decline of population that is a typical phenomenon of the developed world, and in some parts of Asia including Japan and elsewhere, has some

explanations. Reasons for fertility decline include behavioral mechanisms that involve changes in reproductive habits such as the use of contraceptives, induced abortion, and postponement of marriage and motherhood. The other reasons for fertility decline are mortality decline and improved survival—thus no demand for another child, changing demand for children due to the state of the transition of children from being an economic asset to liabilities (mainly in developing countries), and the diffusion of new ideas. Despite the observed tendency of a decline of

fertility, however, the world population will continue to grow, and for the most part this will be the case in the developing world.

The historical account of human population reveals that the size that had been stable to about 300 million during the first millennium had changed beginning from the Renaissance period, and showed a significant increase by the 19th century that was positively associated with economic prosperity. During the 20th century, population growth continued to be witnessed, and toward the end of the century, the steady unprecedented rate of growth of population that had become a social phenomenon of the developing world was viewed as a societal problem, calling for intervention programs. Sub-Saharan Africa is in the lead for the highest rate of population boom. To the contrary, now, at the onset of the 21st century, the developed world is characterized by a decline of its population compared to its counterpart in the Southern hemisphere. The projection indicates the continuation of this trend into the next decades.

Impacts of Population Explosion

The population of a nation is a human asset that is vital to its survival. But, when it gets enlarged beyond what the available resources can support, then the size of the population becomes a problem. In the context

of the developing countries, in particular, the trend of an alarming population growth rate brings about impediments to economic prosperity as it constrains the improvement in the provision of basic services such as education, health, land for food production, and other services. This is mainly due to the reason that the greater the number of the people, the higher will be the demand for food, water, education, health care, sanitary infrastructure, and jobs, as well as a greater pressure on the environment.

Specifically, the concern about population explosion is associated with the following: the worsening of water scarcity, respiratory health complications in cities, a growing malnourishment worldwide, failing economies where the poor are getting poorer, the depletion of oceans due to over-fishing, the inundation of the wild habitats of animals and plants by human activities, the spread of diseases accelerated by crowding, migration pressures, and civil conflicts over meager resources that lead to instabilities and political turmoil.

By being overpopulated, humans unfairly share the resources of the Earth vis-à-vis other species, and destabilize the ecosystem. The exponential rate of growth of population is putting tantamount pressure on the natural resources of the planet. In return, the depletion of the support system in the ecology such as water, soil, plants, and animals constitutes one of the direst challenges to the existence of humanity itself. In some parts of the world, specifically in Sub-Saharan Africa, millions of children are born into starvation. The ecosystem that has been disturbed by humans is leading to factors of further calamity—deforestation, desertification, decreased rain, soil erosion, and little or no yield of food for survival.

The impact of the rapid growth rate of population is viewed as having severe consequences on the environment. There is a gloomy scenario where population growth is taking place: An ever-increasing but poor peasantry depends on the declining natural resources while having a tremendous impact on the ecosystem.

Adjin-Tettey argues that while it is resulting in unwanted consequences for humans themselves, overpopulation is also linked to the reduction in number, and even possibly the tendency of extinction, of some species of plants and animals. Underlining that the growth in population of humans is posing serious problems on the ecosystem, Adjin-Tettey notes that the poor deplete the surrounding supplies, and that

this accelerates the depletion of the world's forest cover that aggravates the rate of deforestation.

The rapid rate of population and its severe consequences is typical in the developing world. The situation is even more pervasive in Sub-Saharan Africa. African population growth rate is less compatible and proportionate to the available services for food, health, and education, and the region's ability to cope with the cycle of poverty. Thus, it is evident that there is a scenario of poor health, low educational achievement, and shortage of food there. Africa's development efforts are dependent upon its measures to overcome its high rate of population growth. African nations suffer from population explosion and, under such conditions, any positive economic growth will not be of great significance as it is divided over an increasing denominator. According to Brown, countries like Ethiopia and Nigeria will double or even triple their population within the next 50 years, and these countries will be in demographic crises.

The projection that African population is likely to double in 2030 is a gloomy scenario unless measures are taken to manage the challenge. Among others, intervention strategies should involve sex education for adolescents and family planning support systems in society at large. The problem requires the political resolve of governments to take all the necessary steps to mitigate the growing risks of population explosion.

Bengtsson and Saito reviewed the historical developments of economic thoughts with regard to the relationship between demography and development. In their review, the authors outline that, following the World War II, the United Nations, politicians, and scholars began to pay attention to population expansion in the developing world. Since then, there has been the belief that because of population expansion, the larger share of production is used for consumption, leaving little for saving. As the result, there will be no capital to develop machinery and infrastructure, which leads to a halt to economic development that brings about poverty. This analysis, according to Bengtsson and Saito, was based on the work of Ansley Coale and E.M. Hoover who studied the development of India. Accordingly, the conclusion was that population expansion provided the work force, and the absence of capital made economic development less possible. Bengtsson and Saito indicate that this pattern of analysis of population expansion in relation to economic growth has influenced the policies of the

UN on population in developing countries to date in its programs such as family planning and investment loans.

Bengtsson and Saito have further outlined the review of the pessimistic view of population expansion. In this regard, they cite the publications of Paul Ehrlich's *The Population Bomb* and Dennis Meadows' *The Limits to Growth*. Both authors, Bengtsson and Saito argue, were convinced that the availability of the Earth's resources is limited to support the increasing global population. In fact, in their later works, Bengtsson and Saito present Meadows and Ehrlich with their continuing optimistic view of population expansion, contending that the catastrophe is taking place as the result of the explosion of the population bomb. Their argument includes an authors' note stating that the population expansion has exceeded the limit in the face of the scarce resources, the proofs of which are hunger, reduction of biological diversity, and the hole in the ozone layer.

Meadows, Randers, and Meadows have recently updated their decades of work in the book entitled *Limits to Growth: The 30 Year Update*. The authors, who have been so influential for many years, maintain their argument and note that there is an occasional catastrophic overshoot that confronts humanity, and the growth in the globe's population is such a case.

The literature on population as a problem has been shifting its focus and framework of argument over the last decades. Prior to World War II, the Social Darwinian and Eugenics schools of thoughts considered the problem of population explosion from the point of view of competitive fertility among various groups of peoples or races leading to the prevalence of fear of being outnumbered by others. In the aftermath of the war, the paradigm was linked to the issues of development. Thus, population explosion in the Southern hemisphere was associated with shortage of food, famine, and failing economy. As the shift of paradigm continued, the environment became the most outspoken rationale for curbing population growth during the 1980s. The issue of population explosion once again came to be associated with gender issues in the 1990s. This has been evident in the debates and arguments observed in the 1994 Cairo Conference. Thus, it is argued, women should be granted the authority and freedom of right to limit birth, and, thereby, contribute to a control on population growth. Curbing global migration and defending international stability are also among the rationales discussed during the last decades for population policies.

Alternative View

Contrary to the position that population expansion is a problem for economic progress, the optimistic line of argument holds the view that population growth is not an obstacle to economic development. One of the earliest challenges to the belief that population expansion is a cause for stagnation of economic growth and poverty came from the work of Simon Kunzets. The work of Kunzets revealed that there is no correlation between population expansion and economic development. Likewise, the work of Ester Boserup provided a strong foundation for the argument that population expansion does not create problems. In fact, Boserup argued that a certain level of population size was an important condition for development to occur in agriculture, and advancements in new techniques and practices were not beneficial until the population had reached a certain level of size and density. According to Bengtsson and Saito, the finding of Kunzets made a remarkable impact and was overwhelmingly popular, whereas Boserup's position on population growth opposed the earlier idea that population expansion is a cause for underdevelopment and poverty.

Similar to the above optimistic view of population, some proposed the perspective that population expansion in Africa is not a problem by itself. To the contrary, the current state of population size can be a compelling reason to look for other ways and means of overcoming the challenge such as creating more markets and technological developments. In this regard, Julian Simon contends that population growth in Africa is a blessing and recommends Africans cope with the situation by creating jobs, marketable skills, and products that would meet demands at an international level. Simon argues that more people induce more demand for goods and services, and that that would initiate more production, which leads to better income for many, and improved standards of living.

This alternative argument upholds the thesis that population by itself is not a dreadful human phenomenon. Furedi takes this position strongly. According to Furedi, the rapid growth rate of population in 19th century Europe, which was linked to economic prosperity, used to be viewed positively. Since the late 20th century, he notes, population expansion in the developing world, which is associated with famine and poverty, is viewed with pessimism as a big social

problem. Furedi notes, therefore, views about population are the functions of the prevailing socioeconomic realities of the period. He justifies this argument as he mentions the case of the 1930s where many thinkers related the crises of the Great Depression in the U.S. with a stagnant rate of population growth. During the same time, Furedi indicates, poverty was considered as the outcome of a slow rate of population growth. In conclusion, Furedi remarks that the causal factor of population growth to economic trend is indeterminate. He attests that the economic stagnation and slow population growth rate of the 1930s was just a coincidence as it is true for today's population expansion and the prevalence of poverty in the developing world. Furthermore, Furedi refers to the case of Europe where millions of unemployed exist at a time when its population growth is below replacement. Population policies in this context are clearly irrelevant to the situation.

For Furedi, population is not number; instead it is communities expressed in the forms of social organizations, political institutions, and technology. Humans are not mere consumers, he remarks, but also producers, and not just as so many mouths, but also as pairs of hands that can produce more foods and enhance the standards of life in their communities. Furedi argues that people encounter poverty not because of numbers, but rather due to lack of influence on their conditions. Famine and poverty facing Africa are not the outcomes of population number, Furedi contends, but the failure of the social system and political institutions. Criticizing the advocates of population policies, Furedi notes that contraceptives can help reduce the rate of fertility, but they do not increase the yield of food; thus, he continues to contend that social and economic changes and progress are more important than the reduction or control of population. In the case of Africa, Furedi notes that economic crises and a high rate of population growth is just that—a coincidence. Africa has plenty of land to engage the energies of its people, what it lacks are the capital and effective political institutions to bring this about. As he continues to elaborate his position, Furedi indicates that what matters most is improvement in the efficiency of institutions, and an emphasis on mere population numbers is, therefore, misleading. He remarks that a decrease in the size of the population is not the solution.

Furedi extends the argument that issues and positions, with reference to population, are political in

nature. He contends that pronouncements on population are rarely neutral statements about numbers. They are usually based on an agenda, which involves issues of resources, power, and national interest. Specifically, Furedi argues that the West has viewed population explosion as problematic. According to Furedi, the central focus of contemporary strategic demography is the contrast between falling birth rates in the North and rising birth rates in the South.

Julian Simon, the renowned optimist, argues that the rapid process of modernization, and changes in the economic systems of India and China at the end of the 20th century, demonstrate that population explosion is not a problem by itself. He notes, instead greater population size promotes progress. Simon writes, "... the size of the human population ... together with the technology these people produced—is the root cause of the speed of progress." For Simon, this is the basis of advancement.

The pressure on resources due to population expansion, the optimists note, is temporary and invites human creativity and problem-solving ability to devise coping strategies. In fact, they argue the problems can lead to the discovery of better ways of handling and managing the encounters of day-to-day life. Explaining the positions of the optimists, Leisinger, Schmitt, and Pandya-Lorch write that the problem of scarcity in society is momentary. In the long term, the impact is positive, as people continue to be inventive and respond intelligently to new demands and circumstances.

In conclusion to their review, Bengtsson and Saito show that in the past, populations have been vulnerable to economic crises, and various methods of easing the pressure on resources were employed, including postponement of marriages and births, and out-migration. The writers, however, underline that it is a rare phenomenon to find a population that expanded beyond the capacity of its resources. While accepting the possibility for population-related problems in the future, the authors nevertheless pointed to the flaw in the Malthusian notion of population as they conclude, "... only that human responses to stress so far have been more varied and flexible than ever Malthus anticipated."

Optimists reject the pessimists' consciousness of limits to growth. The position of the optimists adheres to the accounts of the advancement of human civilizations, in the face of the countless challenges, that led up to the contemporary remarkable age of technology.

Despite the harshness of nature since the time of life in a cave, the ingenuity of humankind has overcome those difficulties so much so that the Internet brought about the realization of the global village. The attained prosperity of the long past and the continuation of its trend into the future adds up to the optimism in which the human race shares the fruits of accumulated wisdom as well as the burdens of difficult times from possible pressures from the expansion of populations.

The Case of Ethiopia

Since the late 20th century the concern over a rapid rate of population growth is being seen as most alarming, among all regions of the world, in Sub-Saharan Africa, which includes Ethiopia. Ethiopia's population is growing fast, and is estimated at the moment to be over 70 million. Though there has been a sign of decline, fertility rate during the 1990s has been above 7.5 children per woman with a growth rate of 3% annually. It is projected that the population will at least double by the year 2030. With such a trend, the state of population expansion in Ethiopia will pose a burden on the environment and food production. Agriculture is the mainstay of the country's economy.

Cognizant of the situation, the Ethiopian government formulated a National Population Policy in 1993. The policy outlines that demographic and development factors reinforce each other. High fertility and rapid population growth exert negative influences on economic and social development and low levels of economic and social development provide the climate favoring high fertility and hence rapid population growth.

The goal is, the general objectives of the policy states, to close the gap between high population growth (total fertility rate of 4.0 by 2015) and low economic productivity through planned reduction of population growth and increased economic returns. This national policy is further reinforced by the expectations on the part of the United Nations that the implementation of family planning is considered crucial to promote depopulation so that Ethiopia will become less dependent on foreign food aid.

However, a decade after the launching of the national policy, the growth of the Ethiopian population is still high. It is believed it could lead to massive

deforestation, soil erosion, and additional burden on the agricultural land, which all together lead to the aggravation of the problem of food security. Basic services of education, health, and a supply of clean water will also be undermined under the circumstances of unchecked population growth amidst a recurrent drought and famine that have aggravated poverty in the country over the last decades.

Others, however, argue that the cause for famine in Ethiopia is not population, but rather subsistence and a fragile economy. Ghelawdewos Araia, though he believes that it aggravates other multivariate factors, notes that population explosion is not the main cause for, it is rather the absence of development that leads to, the Ethiopian famine. Ghelawdeows Araia agrees with the notion of the impact of overpopulation on the environment and the need for family planning to check high fertility rates. However, he underlines that unless sound development programs are in place, a reduction in fertility rates by itself will not prevent famine. Underdevelopment and poverty, Araia underscores, have led to the depletion of the environment in Ethiopia as the peasants cut trees for fuel wood as their main source of energy. Araia concludes by stating that the problem of population can be handled through development efforts that target human resource and sustainable economic growth.

The stress posed on land distribution, and on food yield, due to a rapid growth rate of population, is indisputable. The land distribution, which sustained the food supply for decades, is now dwindling with the rise of the number of family members among which that piece of land must be shared. Today the land holding is less than one hectare per family in Ethiopia. The government has taken the step of formulating a national policy on population issues. But, the implementation of the policy is subject to the initiatives and commitment taken at all levels and among various sectors. Success of population policy in Ethiopia is also partly a function of dependency on foreign aid to run programs such as family planning.

In conclusion, irrespective of the strengths or limitations in their methodological framework or otherwise, both optimist and pessimist arguments about population growth share in common the concern for the good of humanity. In any case, concerted efforts directed at health and population education, sound policies of integrated sustainable development,

expansion of the private investment sector, peace and stability, efficiency of institutions, and financial and technical assistances, would ultimately contribute to the attainment of food security and self-sufficiency in Ethiopia and elsewhere. To that end, the successful implementation of the integrated poverty reduction and development program the government is launching at the moment is among the promising interventions.

POSITIVISM

Positivism is a philosophical movement and a system of ideas that includes a broad methodological approach and a theory of knowledge, in particular of a scientific knowledge, based on radical empiricism that confines knowledge to observable and verifiable data. It has emerged as a fundamentally new, non-metaphysical (“positive,” in a sense of a quality or state characterized by certainty, acceptance and affirmation) philosophy, especially philosophy of science and social science. This conception must have declared as false and senseless all traditional problems, concepts, and propositions of philosophy inasmuch being of abstract nature and unsolvable by experience. It must have rejected as unscientific and meaningless also any type of theoretical scientific thought, not to say any intuition or revelation, considering it a pure and empty speculation.

Human thought, legitimately represented only by logic and mathematics, must strictly and firmly stick to what has been, or in principle can be, experienced and evidenced by given “positive” facts. Such a thought would encompass “positive” information derived from observable experience. Thus, even though the French philosopher and social theorist Isidore-Auguste-Marie-François-Xavier Comte (1798–1857), who coined the term, is generally recognized as the founder of positivism, its roots can be traced back to the epistemology of British empiricism as contained in the works of F. Bacon, G. Berkeley, and D. Hume, according to whom knowledge should be fully grounded in experience, that is, we should not take as knowledge what has not been perceived or cannot be perceptible by senses. In such a way positivism pretends to express the true spirit of science. It represents an attempt at exact methodology of science and true scientific philosophy. Science, especially natural science, is regarded as the paradigm model of a true knowledge and a model for philosophy as well. Even philosophy itself must become a “positive philosophy,” (that is, a philosophical science based on experience and “positive” science). Comte’s monumental six-volume *Cours de philosophie positive* (*Course in Positive Philosophy*) was an encyclopedic project comparable to that of the *Enlightenment Encyclopedists*, in which he developed a complete system of philosophy to provide the foundations for the social order he envisaged.

The story of positivism has embraced a wide variety of ideas not fully endorsed by all of its proponents. Historically, there have been three phases in the development of positivism, each of which has provided a special form of the positivist doctrine. The classical positivism of Comte represents the first phase, which in a sense is still the outcome of the Enlightenment. It can be labeled as the “social P.,” since its originator intended via his conception of a “positive knowledge” not only to provide a true scientific knowledge but also to put this knowledge in the service of human social progress. Comte contended, together with Claude Henri de Saint-Simon (1760–1825), for whom he worked as a secretary for a couple of years, that the social evolution could be achieved through education and enlightenment, i.e., knowledge and science. The social reconstruction presupposes the reconstruction of sciences first. Classifying the sciences according to their degree of increasing complexity, Comte reduces them to six in the following order: mathematics, astronomy, physics, chemistry, biology, and sociology. Thus Comte had conceived the idea of a new science of society, sociology—or “social physics” in his terms—since he thought that there should not be any substantial difference between this and other natural sciences. As the basis for such a positive knowledge of human society and history, Comte considered laws. He divided the social physics into the “social statics” providing social facts associated in the social order with laws, and “social dynamics,” providing the laws of social evolution resulting in the social progress. Thereby such a science would provide the foundation for social reconstruction. Comte believed in the spirit of the enlightenment: that political problems should be subject to the same procedures that scientists use in order to resolve scientific questions, i.e., that politics should become a sort of “social engineering,” or “social technology,” or perhaps applied social science, which is to be implemented by experts and technicians, who fully understand its subject. In a sense, Comte shared with F. Bacon not only his empiricism but also his pragmatism. He worked diligently to see his ideas be useful in practice. In order to persuade himself and others that his theory is also a part of the social process, he developed the quasi-Hegelian evolutionary scheme of the history of human civilization, according to which the human mind, knowledge, and society have passed through the following three stages, as he put it in his work, *The Discours sur l'ensemble du positivisme*

(*A General View of Positivism*) published in 1848: “[T]he *Theological stage*, in which free play is given to spontaneous fictions admitting of no proof, the *Metaphysical stage*, characterized by the prevalence of personified abstractions or entities, and lastly, the *Positive stage*, based upon an exact view of the real facts of the case.” That is, the Theological stage was dominated by religion and explanations of natural phenomena by theology; the Metaphysical stage was dominated by obscure abstract concepts and explanations of natural phenomena by philosophy, and the Positive stage shall be dominated by positive knowledge and explanations of natural phenomena by positive science. The first stage represents the “infantile” stage with the primitive, supernatural worldview; the second stage represents the “adolescent” stage with the reference to invisible natural essences, and the third stage represents the “mature” stage, corresponding to the present time, in which the world is conceived as a whole and as an ordered organism governed by necessary laws. Strangely enough but true, Comte, in the later period of his life, and substantially due to a 1-year-long personal affair with Clotilde de Vaux (1815–1846), switched from his hard-nosed scientism toward the recognition of the emotional side of human life, including love, friendship, and altruism (of the latter term he is said to be the originator). He founded a “positive religion,” which he named the “Religion of Humanity” in order to establish even an emotional and spiritual foundation for his philosophy—something he formerly would have strongly dismissed. However, this was in line with the development of his thought, since subsequently he placed ethics on the highest step in his hierarchy of sciences. He suggested that altruism combined with rationality may bring the highest stage of social evolution, and thus he aimed to top his project not only with general social ethics, but perhaps also with general social anthropology, as he mentioned in the popular introduction of his system of 1844 *Discours sur l'esprit positif* (*A Discourse on the Positive Spirit*). Humanity has now become the “God” of positivism and the object of worship. Humanity with the world-space and the earth has formed the positivist trinity. Comte even strived to make his secular religion complete with the temple, pontiff, priesthood and its calendar of saints. After the death of Comte, a split occurred in the school of positivism, and in France two groups had been formed: an orthodox one led by Pierre Laffitte (1823–1903), and

a dissident one led by Émile Littré (1801–1881). Other important proponents of the first phase of positivism were John Stuart Mill (1806–1873), Herbert Spencer (1820–1903), and Alexander Bain (1818–1903) in England. They focused on the theory of scientific knowledge and theory of society. The principles and spirit of classical positivism no doubt pervaded the scientific and philosophical thought in the 19th century and exercised a broad influence in many spheres.

The second phase of positivism, “Neo-positivism,” which can be labeled as “critical P.” (sometimes as “empirio-criticism”), focused on an immediate experience and its inception dates back to the 1860s–1870s. It is associated mainly with the Austrian philosopher and scientist Ernst Mach (1838–1916)), according to whom it is also called “Machism,” and some of his Austrian colleagues such as Richard Avenarius (1843–1896), but also with J. H. Poincaré (1854–1912) in France, and others. These thinkers have not so much in common with the classical Comtean positivists; nevertheless, there are some features in their works that allow one to describe them as participants in the same movement. Thus they were also basically motivated with issues of scientific knowledge and methodology. However, their extreme empiricism brought them to psychologism of the type of J. S. Mill, and even more radically to subjectivism of the type of G. Berkeley. Rather than general sociology, they were interested in a general theory of economics.

The most recent and third stage of P., sometimes also called “Neo-positivism” by those commentators who simply decide to ignore the former Machian stage, also has its several labels such as “logical positivism” (most often) or “logical empiricism,” or “logical atomism” as its special variant. Its origins are firmly linked up with the so-called Vienna Circle (at its beginnings were also influenced by the home “gurus” such as Mach and Avenarius), which started to work as early as in 1907, but was made complete in the 1920s by assembling a whole range of natural and social scientists who gathered to discuss the typical positivist agenda of the philosophy of science, and who have marked substantially the developments in this area for the long decades of the first half of the 20th century to come. The group included such important figures as Moritz Schlick (1882–1936), Otto Neurath (1882–1945), Rudolf Carnap (1891–1970), Philipp Frank (1884–1966), Hans

Reichenbach (1891–1953), Herbert Feigl (1902–1988), Kurt Gödel (1906–1978), Hans Hahn (1879–1934), Carl Gustav Hempel (1905–1997), Friedrich Waismann (1896–1959), and others, including loosely also Ludwig Wittgenstein (1889–1953), Alfred J. Ayer (1910–1989), Karl R. Popper (1902–1994), and Willard V. O. Quine (1908–2000), as their partner-discussants and successors, respectively. In due course these thinkers have concentrated on the philosophical problems of language, symbolic logic, the structure of scientific investigations, and so on. They came to oppose psychologism, which they replaced by their logicism, and finally gave rise to another important philosophical movement of the 20th century, with which they have been intertwined, i.e. the analytic philosophy in the broad sense. In comparison to both previous stages of positivism, this one has put emphasis also on logic, whose role they understood as the formulation of a priori rules of valid inference in science, and explication of basic scientific concepts (which they called “the logical analysis of scientific language”). Philosophically, the crucial intention of these positivists was the elimination of metaphysics, a task they intended to accomplish via applying scientific methods to the analysis of language of science and philosophy. As the main instrument for this purpose they selected their self-invented “Verification Principle.” According to this principle, there are just two types of meaningful propositions: tautologies (true by definition), and those verified and/or verifiable by empirical methods of science. All other statements must be pseudostatements lacking a meaning. Such, for instance, are metaphysical and/or theological statements, being neither true nor false, but “nonsense.” The fatal trouble, however, has appeared for the logical positivists with the Verification Principle itself: it is the statement, which cannot be verified by using its own criteria. The suggestion provided by K. R. Popper to replace the principle of verification for the fallibilist principle of falsification has brought better results. After the tragic assassination of M. Schlick, the leader of the Circle, and the rise of Nazism in Germany, the final phase of this movement continued in the United States, prevailing under the title of logical empiricism. One of the main ideas they took over from Europe, and attempted to maintain during and after World War II, was the idea of a unified science that they were developing within the project of the multivolume *International Encyclopedia of Unified Science*. This was based on

the doctrine that there is a universal scientific method, which can unite all science, natural and social, and that all real science must conform to this methodological model. Thus, particularly in the fields of social science, including humanities and anthropology, such approaches as naturalism, reductionism, behaviorism, operationalism, methodological individualism, and formal and statistic methods have been supported at the expense of, and directly in the opposition to, interpretive and hermeneutic approaches. The focus on explanation versus interpretation has long prevailed, as well as the idea of value-neutral science among the logical empiricists.

Despite the considerable legacy of all phases of positivism, in particular in sociology, methodology, and philosophy of science, the second half of the 20th century has witnessed its final stage and the gradual replacement by what now is called “post-positivism.” Its rise is associated mainly with such figures, formerly members of the logical positivist group, as Thomas Kuhn (1922–1996), among others. Traditional methodological dualisms of analytic and synthetic theory and observation seem to have been explained as untenable by W. V. O. Quine. Such an approach attempts to embrace and preserve the scientific values and norms of rationality, while describing them in a new, non-dogmatic, historical, contextual, conventional, communicative, and more creative mode. The post-positivists do not ignore as scientifically irrelevant such factors as historical, anthropological, and cognitive factors, including psychological ones that influence the whole science, not merely the social science. The traditional specters of positivism, such as values, meanings, and interpretations, seem to be thus no more haunting, which may be read as a good message for anthropology from the part of this current, and seemingly the “fourth,” stage of positivism.

POSTCOLONIALISM

One of the basic principles of postcolonial thinking is that you really should not say, “one of the basic principles of ‘X’ is ‘Y.’” Postcolonialism, in its epistemological orientation, stands against what it labels “essentialism,” the identification of central or core characteristics, particularly of peoples, societies, and cultures. However, adhering to this prohibition makes it difficult to identify and discuss anything, including postcolonialism.

In postcolonial thought, there is good reason to reject essentialist characterizations of peoples, societies, and cultures. The reason is that, according to postcolonial thought, “knowledge is power,” but not in the traditional sense of knowledge giving one real understanding of the world, gives one power in the world. Rather, the postcolonial view, following Michel Foucault, is that “knowledge is power” in the sense that what we call “knowledge” is really constructed ideology with no grounds in reality, which is designed to justify the imposition of power over others, to repress and exploit others for fun and profit. Of course, this other postcolonial epistemological principle, that true knowledge does not exist, raises the same kind of awkward question that arises with all relativist theories: must postcolonial doctrines and assertions, like those to which it directs its critical attention, be considered “constructed ideology

with no grounds in reality which is designed to justify the imposition of power over others?"

Postcolonial thought has developed in the context of the confrontation of cultures. Its stance is critical toward imperialism and colonialism, especially European imperialism and colonialism. For example, according to Abdul Jan Mohammed, "Motivated by his desire to conquer and dominate, the imperialist configures the colonial realm as a confrontation based on differences in race, language, social customs, cultural values, and modes of production." Essentialism is used to define imperial and colonial subjects as different, as "the Other" (as the postcolonialists would say), and to contrast the culture, economy, politics, science, and so on of Europe favorably in comparison.

Postcolonial thought manifests itself in many contexts and is applied in many fields. As Stephen Slemon explains, postcolonialism has been used as a way of ordering a critique of totalizing forms of Western historicism, as a portmanteau term for a retooled notion of "class," as a subset of both postmodernism and poststructuralism (and conversely, as the condition from which these two structures of cultural logic and cultural critique themselves are seen to emerge), as the name for a condition of nativist longing in postindependence national groupings, as a cultural marker for nonresidency for a third-world intellectual cadre, as the inevitable underside of a fractured and ambivalent discourse of colonialist power, as an oppositional form of "reading practice," and, as the name for a category of "literary" activity which sprang from a new and welcome political energy going on within what used to be called "Commonwealth" literary studies.

In anthropology more specifically, postcolonialism has two main thrusts: First, again at the epistemological level, it challenges anthropological research in "other" cultures, attacking both the authority of anthropologists to speak for other cultures and essentialist descriptions of those cultures. Postcolonial preferences in reporting on other cultures would be for an emphasis on "voices" of the subjects themselves; that is, instead of commentary and analysis by the anthropologist, ethnographic reports would consist of comments and commentaries by the "natives."

Second, at the level of social and historical analysis, anthropologists of postcolonial bent would de-emphasize focus on characteristics of the local or

regional indigenous culture, and instead analyze the ways in which European imperial and colonial power distorted and corrupted indigenous culture, and exploited and oppressed imperial and colonial "subjects." In postcolonial analysis, culture and social organization that may at first appear to be indigenous, and above all social and cultural problems, whether in economics, politics, human relations, gender relations, human rights, and so on, can be traced to externally imposed imperial and colonial impositions.

Perhaps the most important postcolonialist influence on anthropology has been Edward Said's *Orientalism*. Said, a professor of English at Columbia University, argued that Oriental Studies, the field of historical, literary, and cultural examination of the Middle East, consisted not so much of dispassionate, reasoned, objective understandings of the Middle East, but rather a set of fantasy projections, distorted disparagements, and demeaning misrepresentations, the real purpose of which was not to understand the Middle East, but to justify and encourage European conquest, oppression, and exploitation of the Middle East and its peoples. From this perspective, any critical comment directed toward the Middle East can thus be dismissed as "Orientalism." Said's critics argue that Said violated his own strictures in his account of Oriental Studies, and accuse him of "Occidentalism." Said, from a privileged family of Palestinian origin residing in Egypt, presented himself as a Palestinian refugee and adopted the Palestinian cause as his heartfelt political commitment, influencing many in academia to side with Palestine.

Two important intellectual streams converge in postcolonialism. One is Marxism, and particularly Leninism. Marxism was a great political influence in the second half of the 19th century and the 20th century, and became a major academic influence as well. Popular in Europe throughout the 20th century, Marxism became influential in North American academia during and after the 1960s. But with the decline and fall of the Soviet Union and communism in the late 1980s, Marxism lost some of its luster. Lenin's *Imperialism*, which updated Marx by applying his theory to the wider imperial and colonial fields, has continued to be an inspiration. Postcolonialism, without acknowledging its debt too explicitly, has drawn on Marxism and Leninism, although, like Foucault, a more modern and direct influence on postcolonialism, stressing power more than the economics emphasized by orthodox Marxism.

The other stream converging in postcolonialism is postmodernism, arising in anthropology from cultural and symbolic anthropology; it takes the epistemological stand that everyone is “positioned” and can only see a particular point of view, rendering all opinions “relative” and “subjective.” There is, thus, no objective knowledge, and one view (or custom, practice, culture, or society) is as good as the next. Postcolonialism applies this precept to Third-World societies.

For postcolonialists, anthropology cannot fulfill its “modernist” or “realist” objective of discovery and accurate representation. According to the postcolonial vision, Western anthropologists—epistemologically hampered by cultural blinders, and guilty of colonialist crimes—can legitimately only advocate on behalf of the colonial oppressed, the subaltern, the disadvantaged, while at the same time condemning their oppressors, European and American imperialists and advocates of capitalist globalization. Indeed, under the influence of postcolonialism, much academic anthropology has discarded aspirations of a scientific nature and taken on the character of political advocacy.

POSTMODERNISM

In few areas is it more problematic to arrive at a clean definition than it is for postmodernism. Not the least of the problem is the resistance among postmodernists themselves to be defined, or, in many cases, to

admit the authority or even the possibility of definition as an activity. Before attempting a definition, a series of useful distinctions can be drawn.

Postmodernity and Postmodernism

The first important distinction to be made is that between postmodernity and postmodernism. Postmodernity is a name given to a period of history, and postmodernism is the body of theory that has developed to explain that period. Opinions differ about when postmodernity is supposed to have begun, with dates varying between 1968 and 1973. All agree that conditions in the world have changed since then. In international politics, the sites of authority have fractured from the relatively straightforward conflict of the Cold War to the multi-polar, less predictable, and more confusing international situation of today. Other fundamental changes have been made to our styles of work, with entirely new industries, work hours and arrangements than was the case before. The assumption underlying the notion of postmodernity is that the world has seen not simply changes in style, but also a fundamental shift in the way the world operates, a shift which has been to the disadvantage of predictability, order, and rationality.

Those who argue for 1968 as a convenient date for the onset of postmodernity point to the student riots of that year, when the baby boomer generation, the best-fed, best-educated generation in world history, spurned the cultural conventions they grew up with, and demanded change. These revolts did not demand a specific set of political, social, and economic changes; they demanded *change*, as a general rejection of the old.

The impact of the baby boomer generation is very significant, but even it was swept along by the broader transformation occurring after the events of 1973. This was the year of permanent international economic change resulting from the oil shocks triggered by a newly radicalized Organization of Petroleum Exporting Countries (OPEC). The oil shocks were provoked by the oil-producing countries, most of which were from the Muslim world, wanting to express anger at the continued support by the West for Israel, which had been decisive in the recent Yom Kippur war. This marked a fundamental change in the balance of economic and political power marked by a dramatic shifting in priorities in global politics and economics. The widespread social changes that

have occurred in the West are largely a product of these developments. Postmodernity can best be dated, therefore, from 1973.

It is important to note that “postmodernity,” as discussed here, is nothing more than a title given to a period by historians, like “Renaissance” or “Dark Ages.” Others have called this period Late Capitalism. Still others have rejected the idea that the events of 1973 mean we can no longer speak of “modernity.” This debate becomes a question about the periodizing of history, and the usefulness of such a procedure.

Postmodernism as a Series of Reactions to Postmodernity

We have seen, then, that postmodernity and postmodernism are not related. Postmodernism is, as the suffix implies, an “ism,” a series of reactions that have arisen to explain the times known to some as postmodernity. It is quite consistent to see value in postmodernity as a historical term while also rejecting the postmodernism that has arisen as a series of reactions to explain postmodernity.

Most introductory essays to postmodernism begin with the insistence that any attempt at a comprehensive delineation and understanding of postmodernism is inherently contradictory and bound to fail. To overcome this problem, most characterizations of postmodernism portray it as a less coherent body of doctrine as a general mood, or, as described in the previous paragraph, a series of reactions. The series of reactions are often expressed in negative terms.

Postmodernism is almost entirely confined to universities and literary circles. And within universities, some faculties are more likely to be favorable to postmodernism than others. Most branches of the sciences are hostile, whereas departments of English or French literature, architecture, visual arts, and occasionally anthropology and sociology are more likely to react favorably. Opposition to postmodernism in Philosophy departments, particularly in English-speaking countries, has grown since the mid-1990s.

As well as these divisions between faculties, there is also a division based on geography. We have already noted this division among philosophy departments at universities. There are two general strands to the postmodernist reactions to postmodernity. One strand of postmodernism is content to *acknowledge* the changes that have occurred since 1973 and to try to understand them. The other, more radical strand

is more willing to *celebrate* those changes. Broadly speaking, this fissure divides postmodernists in the Anglo-American academic community from those from the Continental (mainly French) academic community.

This is made more complicated when we note that this division is by no means exclusively geographical. The two styles of postmodernism, while having a geographical dimension, are principally divided by a series of contrasting emphases with regard to some important questions. The first of these dividing points centers around attitudes toward philosophical analysis. Anglo-American postmodernists may be cautious about analysis as a tool, but still acknowledge its value. Postmodernists of the Continental variety, by contrast, are more inclined to view analysis as part of the problem they are looking to overcome, rather than as a useful tool to gather new and better understandings.

A second major area of divergence can be seen in the attitudes toward metanarratives. Most postmodernists, whether Anglo-American or Continental, see postmodernity as a time when traditional metanarratives dissolved. A metanarrative is a general intellectual framework through which we view history. For example, the communist metanarrative is of a progressive, and inevitable, succession from feudalism, through capitalism to socialism, and, in the future, on to communism. A Christian metanarrative, by contrast, proceeds from a primitive innocence in Eden, followed by the Fall and the condition of sin and death among humans, relieved by the redemption of Jesus Christ, and which will be brought to an end when Christ returns to reward the faithful and judge the damned. The most oft-quoted definition of postmodernism comes from the French thinker Jean-François Lyotard, who defined it in terms of incredulity toward metanarratives.

The differences lie in their contrasting attitudes to the end of metanarratives. As noted above, most postmodernists from the Continental tradition are likely to celebrate the end of metanarratives. They claim that not only are metanarratives no longer needed, they are no longer welcome. The end of metanarratives brings the end of the tyranny of history, and, more particularly, the end of the presumption of scholars to be chroniclers of historical fact. Instead, postmodernists argue, we have a mass of assertions and claims, which can all compete for our attention as best they may, with little difference in the outcome of one being chosen over another.

Underlying this hostility to metanarratives is the postmodernist hostility to what they see as the dominating and bullying nature of science and reason. The central claim of postmodernists of the Anglo-American strand is that rationality is a historically conditioned faculty, which means that different historical epochs will produce different notions of rationality. This is a point few opponents of rationality would dispute. Indeed, many of the people derided by postmodernists, such as Bertrand Russell, made these points long before postmodernism was an intellectual force.

Others, usually of the Continental strand of postmodernism, are more extreme, and seek to condemn what some call “legislative reason” as being inherently domineering and oppressive. In contrast to this, they regard postmodernism as a liberation from rationality because it is a liberation from all socially constructed bounds and norms. As one prominent postmodernist stated in 1992, postmodernism is about splitting the truth, the standards, and the ideal into what has been deconstructed and into what is about to be deconstructed, and denying in advance the right of any new doctrine, theory, or revelation to take the place of the discarded rules of the past. David Harvey, from an influential postmodernist work from 1991, enthused that postmodernism wallows in the fragmentary and chaotic currents of change as if that is all there is. In a similar vein, Gregory Bruce Smith identified postmodernism as fundamentally a sign of disintegration, transition, and waning faith in what he called the Enlightenment project.

In defining postmodernism, then, we need to take account of these two strands of interpretation. The more moderate version of postmodernism is the assertion that we cannot *know* anything, but can only interpret, and that any interpretation we make can only express our partial and narrow perspectives. The more radical version of postmodernism is the assertion that not only can we not know anything, but that also any claims to knowledge are bound to be hegemonic and impatient of dissent, which means that our ability only to interpret from our partial and narrow perspectives constitutes a liberation from that tendency toward hegemony, which is particularly evident in science and rationality.

Behind the differences of emphasis and geography, there is a common political heritage for much of postmodernism. This is because postmodernism is a phenomenon of the political left. The reason why postmodernists are anxious to write the obituary of

metanarratives is because many of them were, earlier in their lives, proponents of variations of socialism and communism, which, as we have seen, have strong metanarrative components. This can be traced back to the disillusionment of German socialists after the failure of the Spartacist revolt in Berlin in 1919. Not only did the socialist revolution fail, but also the parties of the left were then seen to fail as well, as they showed themselves incapable of resisting the rise of Nazism. By their slavish following of the dictates of Moscow, the parties of the left had betrayed their purpose. The school of Marxist-inspired criticism, known as the Frankfurt School, traced the progressive failures of each institution that had once been a source of hope.

After the World War II, the Soviet Union joined the ranks of gods that failed. Between the Soviet invasions of Hungary in 1956 and Czechoslovakia in 1968, the promise of communism as a metanarrative of progressive liberation from alienation became ever more difficult to sustain. The choices of the left after 1968 were stark: acknowledge that capitalism and the metanarratives that sustain it had triumphed, or create a system of criticism that denied the legitimacy of any metanarratives at all. Postmodernism adopted the latter approach.

The differences of emphasis between the Continental and Anglo-American styles of postmodernism were most pronounced on the question of the degree to which Western culture could be salvaged. Critics like Theodor Adorno (1903–1969) and Max Horkheimer (1895–1973) were among the more pronounced cultural pessimists. In *Dialectics of Enlightenment*, Adorno and Horkheimer saw modernity as inherently self-destructive, carrying the germs of its own dissolution and decay. There was a straight line, they argued, from the Enlightenment to Nazism and Stalinism. Later heirs of this high level of pessimism included the Polish born sociologist Zygmunt Bauman (1925–), who argued that modernity is a long road to prison, and Michel Foucault (1926–1984), who saw all society as engaged in a war against people to impose on them a sterile understanding of what it is to be human.

The more moderate postmodernists in the Anglo-American schools, however, were not prepared to go this far. Their general argument was to see value in the humanist tradition of the Enlightenment, merely wanting to excise it of the faults and excesses they perceived it brought with it. Advocates of this approach

include the English philosopher Michael Luntley and the New Zealand sociologist Barry Smart.

Postmodernists agree on their suspicion of meta-narratives, diverging only on the degree of opposition they are prepared to express. Another area of general agreement is in their attitudes toward science. Anglo-American and Continental postmodernists agree that science involves a metanarrative, which they question. The metanarrative of science speaks of cumulative knowledge over time, leading to ever-clearer understandings of the universe. Just as importantly, postmodernists question the claim of science that it is grounded in objective truth. But the attitudes toward science reveal the greatest splits between the Anglo-American and the Continental styles of postmodernism. The Anglo-American attitudes are best articulated in the works of Richard Rorty (1931–) whose critique has been directed against foundationalism, the practice of claiming that one's theories rest on objective foundations of truth.

The Continental branch of postmodernism, once again, has wandered much further afield on its attitudes to science. Indeed, it is in this area that it has provoked the strongest opposition. Working from an epistemic relativism, many Continental postmodernists have pressed the claims that science is a meta-narrative like any other, with no special claims to authority, and indeed, meriting extra levels of criticism precisely because of those claims of authority they perceive scientists making.

The Decline of Postmodernism

Postmodernism began to attract some significant critical attention after about 1994. Much of the criticism was led by scientists and by philosophers who take science seriously. Leading the way was a devastating critique by Norman Levitt and Paul Gross titled, *Higher Superstition: The Academic Left and Its Quarrels with Science* (1994). Other significant milestones included *Derrida and Wittgenstein* (1994) by Newton Garver and Seung-Chong Lee, *The Poverty of Postmodernism* (1995) by John O'Neill, and *The Flight from Science and Reason* (1996) edited by Paul Gross, Norman Levitt, and Martin W Lewis.

The decline of postmodernism was publicized by what has become known as the Sokal Hoax. In 1996 Alan Sokal, a professor of physics at New York University, submitted a paper to the postmodernist journal, *Social Text*. The paper, titled "Transgressing the

Boundaries: Toward a Transformative Hermeneutics of Quantum Gravity" supposedly demonstrated that the laws of science are nothing more than social constructs—one of the central points of Continental postmodernism. The *Social Text* editors made the mistake of not submitting the article to the usual process of peer review, and on the day the article appeared, Sokal announced in the journal *Lingua Franca* that the article was a hoax.

The hoax, and the controversy that followed, was a major embarrassment for the editors of *Social Text*, and for the wider claims of postmodernism to academic credibility. Sokal followed up his hoax with a scorching attack, coauthored with the Belgian physicist Jean Bricmont, on French postmodernism and published in the United States under the title *Fashionable Nonsense: Postmodern Intellectuals' Abuse of Science* (1998).

Alongside this counterattack, some of the more moderate Anglo-American thinkers who formerly expressed support for elements of postmodernism have since stepped back. In Britain, Christopher Norris, a prominent defender of the works of Jacques Derrida, has more recently launched important critiques against the relativism inherent in postmodernist thinking. And in the United States, Richard Rorty, without having changed his position, has expressed his regret at ever having used the term "postmodernist." Most recently a newer movement known as critical realism has arisen as the successor to postmodernism. The intellectual initiative has clearly now passed to the critics of postmodernism.

POTASSIUM ARGON DATING

Potassium argon [K/Ar] dating is a radiometric technique that can be applied throughout the time span of the Earth from 4.5 billion years ago down to a few tens of thousands of years ago. Thus, K/Ar is the method that has been most useful in unraveling the history of the earth, the development of life, and most importantly, the history of human development. The method is based on the properties of potassium, which is one of the most abundant elements of the continental Earth's crust comprising 2.4 weight percent. There are three naturally occurring isotopes of the element potassium: ^{39}K (93.258%), ^{40}K (0.0117%), and ^{41}K (6.73%). The dating technique is based on the radioactive decay of the isotope ^{40}K , which has a half-life of 1.28×10^9 years. Primordial ^{40}K , which at formation would have had an abundance of about 14%, has diminished by a factor of over a thousand in the 10 half-lives since the Big Bang approximately 13 billion years ago, and over a factor 10 because the three half-lives that have occurred since the origin of life on Earth 3.8 billion years ago.

Unlike the radiocarbon dating, where the amount of the cosmogenically produced radioactive carbon isotope remaining need only be compared to its original concentration, K/Ar dating determinations are based on the binary decay of ^{40}K to either ^{40}Ca

(88.2%) or ^{40}Ar (11.8%). It is the steady buildup of the daughter isotope ^{40}Ar that represents the atomic clock and its ticking. The clock starts when a molten rock cools and solidifies, having liberated any former ^{40}Ar , and is read by comparing the amount of ^{40}K present when formed to the amount of ^{40}Ar present (see figure). This comparison is possible because the ratio of ^{39}K to the decaying ^{40}K is known, and ^{39}K is the most abundant stable isotope that can be measured. This technique requires that the ^{40}K , ^{39}K and ^{40}Ar , ^{36}Ar be analyzed separately to produce the data required to calculate an age. The obvious complication of this technique is the fact that ^{40}Ar is an inert gas that makes up 1% of the atmosphere and can diffuse into samples biasing the calculated results. Furthermore, the gas can escape from samples, thus producing apparent younger ages. The modern ratio of ^{40}Ar to ^{36}Ar is 295.5, which permits the analyst to subtract the atmospheric ^{40}Ar from the radiogenic ^{40}Ar in a sample to arrive at the amount produced by ^{40}K decay.

A new approach has been adopted in recent years in which the ^{40}Ar and ^{40}K are measured simultaneously by irradiating the sample and converting some of the ^{39}K into ^{39}Ar , which does not occur naturally. The ^{39}Ar half-life of 269 years is long enough to cause no problems in the age calculations. This approach permits the ^{39}K and the ^{40}K to be directly determined along with the ^{40}Ar and eliminating the need to separately analyze for potassium. The addition of lasers in

place of induction heating technology has permitted more precise analyses to be made. This approach permits the analyses of single grains, and the use of a more refined step-heating approach that greatly improves the reliability of the result and eliminates the need to do an independent analysis for the potassium.

The figure shows the parent-daughter relationship between the radioactive ^{40}K and the stable ^{40}Ar . Only 11.8% of ^{40}K atoms decay to ^{40}Ar .

The potlatch is a winter festival, with ceremonial feasts, where gifts and property are distributed to obtain or reassert a status, where prominent high caste families display crests, where names are given, where solidarity for war was made (in the past), and peace declared, where memorials are given and ancestors are honored. It was a place where "people played stick games in the evening" recounts Elizabeth Woody in her essay, "Tradition with a big 'T.'" Over time the potlatch evolved through external influences, such as a new supernatural encounter, or introductions from surrounding and distant tribes, with European contact being the most dramatic change in ascendancy.

With the introduction of the European culture, a new wealth and merchandise system was instituted, which transformed the very format of the potlatch. Competitive potlatches rose to new heights of property distribution with most tribes, and more dramatically with the Southern Kwakiutl. This drew concern from the settlers and church leaders, leading to local governments petitioning for a ban to all potlatch activities in Canada.

Potlatch is a word derived from the "Chinook" trade jargon, meaning, "to give." The potlatch existed prior to trade with the Chinooks. It existed in a clandestine manner in Canada while outlawed, and is growing in popularity even today. Will future potlatches only be faint echoes of those of the past? Will today's potlatches be the foundation for evolutionary growth in taking this festive occasion into a new modern realm? These are the questions to be answered by present and future generations.

The Potlatch Prior to European Contact

Potlatches were a way of life among the Northwest First People, and were carried on along the Pacific Coast of Alaska to Oregon. They created the impetus for daily activity; they were the economy, the basis for the flow of wealth, and the standard of the class system. Etiquette was not only observed in the

potlatch, but in everyday life, as Stanley Walens reveals in *Feasting with Cannibals*, and was strictly enforced. This ceremony is more famously known through the First People from Southeast Alaska to British Columbia; in particular among the Tlingit, Haida, Bella Bella, Tsimshian, and Kwakiutl. Potlatching was also practiced in the Washington and Oregon coastal villages of the Chinooks, Nootka, Salish, Lummi, and other surrounding tribal neighbors, as well as on the Bering Sea, along the Aleutian Islands and interior of Alaska, by the Aleuts, Athabascans, and Inupiat. These are the peoples who would congregate, feast, and dance, while royally attired in regalia displaying their crests, which were passed down to them from their mother's clan (for those of matriarchal societies) from time immemorial. This took the form of dancing and singing of

19th century bentwood boxes

ancient encounters, as in Pamela Rae Huteson's *Legends in Wood: Stories of the Totems*, which give examples of encounters of transforming beings of the air and land, which could take off their coat of feathers or fur, and appear as human as any of "The People." Culture bearers also brought these accounts through speeches, and even through puppetry during the weeklong celebrations. Secret Societies of Dog Eaters and Hamatsa Cannibal Dancers became infamous for their rituals. Those with higher rank utilized the potlatch to keep their standing, since castes were fluid, and it was easier to move down in rank than up.

Potlatch Preparation

The potlatch was a complex feast, even a symbolic feast such as a marriage or funeral, and could have underlying intentions or ambitions for the individual or clan sponsoring the celebration. There were five steps to take in preparing for a potlatch.

1. Alliance would be made within the clan itself. Labor was required for the amassing of the great amounts of food required to feed large numbers of people for several days, and to choreograph the uses of the houses where distinct feasts would be held. Canoes, Chilkat blankets, bentwood boxes, and baskets were often commissioned and produced for the occasion.

2. Alliances could come from other clans for labor and contributions. In tribes with two main clans, the opposite clan, George Thornton Emmons found, would "take over" the funeral processes and longhouse

building for instance. They would also be paid for this service with gifts during the potlatch.

3. Consideration would be made for invited guests. The larger the audience gathered to witness the event, the more direct was the reflection of the status and prestige of the sponsor and verification, to witness, the claims of property. Guests would be paid with gifts to witness the payment for the services rendered by the the opposite clan, and of status and property claims.

4. The production of gifts, and the procurement of food (which also served as part of the gifts), was also very important. It could take years to accumulate presents to be distributed. The entire clan would participate in some aspect of gathering and producing. Totem poles and longhouses required forest materials of specific dimensions, and so these had to be sought out and retrieved.

5. Regalia, including masks and/or other attire, had to be constructed for the performances, and the accompanying songs and dances had to be rehearsed. Dancers who performed incorrectly were regarded with great shame.

Drums sounded to announce the commencement of the potlatch. When the guests entered the longhouse, at times paddles would appear first through the doorway opening. “The men folk came through first with the paddles. Others hid knives in their blankets, when they came in the house dancing. They did this to protect the women and babies,” explained Eleanor Peratrovich, Tlingit elder from Klawock, AK. Although a potlatch was a festive occasion, it could also be staged for revenge of an ancient wrong.

A formal speech would be made from the sponsor of the feast, usually the Chief. A declaration for the reason of the potlatch, as well as the history and rights of the clan would be made. Seating arrangements were strictly adhered to; placing a high caste person in a lower position was considered an

insult. Several masters of ceremony could administer over the feast, ensuring the rank of speakers and performers. Food was served in bowls belonging to the clan, intricately carved with representations of stories, images, and property; the Tlingits called these precious items “at.óow.” Some bowls could be as long as a canoe, as in the case of the Wild Woman of the Woods bowls and the Woodworm dish of Klukwan. The feast alone could last half a day, requiring those in charge of the needs of the guests to provide special services of hospitality and attention. An extreme display of wealth in a competitive potlatch could involve eulachon oil dripping from the smoke hole into the fire, breaking copper shields or throwing them into the water (called drowning a copper), burning canoes, and even the killing of slaves.

Ban of the Potlatch

Inflation hit the Northwest Cultures as villagers obtained an easier source of prosperity, enabling them to access all ranks. For example, a traditional Chilkat or Raven’s Tail Blanket entailed a considerable amount of time to gather materials and weave, while a Hudson Bay Blanket was comparatively inexpensive, and became a new way to assign value to objects (for example, copper shields). commanded 75,000 Hudson Bay Blankets as a purchase price. Prosperity increased as villages declined in numbers due to the ravages of European diseases, making it possible for new elite positions to open to those who previously were denied the opportunity to progress in class standing. Chiefs scrambled to prove their rights and position with abundant property displays (e.g., a successful sealing season could create enough wealth for a person to buy a coveted social position), as a breakdown of their socioeconomic cultural system encroached on their society’s power and control.

Competitive potlatches in Kwakiutl Country infuriated Canadian European settlers and church leaders like the Reverend and Mrs. A.J. Hall, who actively sought to quash the potlatch altogether. Additional misunderstanding of the “cannibal” performances,

Sheet’ka Kwaan Naa Kahadi Tribal Community House Performers at Sitka, Alaska

Source: Photograph by Pamela Rae Huteson.

and other aspects of the potlatch process, culminated in the 1885 Canadian Law banning the potlatch. The enforcement of this law further contributed to the cultural genocide of the Canadian First Nations People. Aldona Jonaitis posits the following reasons for the decline of the potlatch: 1) Alterations in the structure of the fishing industry, 2) The depression, 3) Anglican persuasion, 4) Pentecostal evangelization, and 5) Lack of interest among young people.

Zealous arrests were made after potlatches, and the confiscated potlatch paraphernalia were sold to museums; which made William H. Halliday, Canadian government agent, consider the potlatch “dead.” The Elders lamented over this ban, while at the same time some Christian villages, like the Kispiox on the upper Skeena River, banned the potlatch and even posted their own Potlatch Prohibition Warning Notices.

This was the darkest period in potlatch history. Many Kwakiutls went underground with their potlatches, and incorporated giving with other celebrations.

The Potlatch Today

In 1951 the Potlatch Prohibition Law was lifted. Memorial and wedding potlatches were the first to resume in the villages; some had not held a potlatch for nearly a century. It was necessary to call on the Elders' wisdom and memories for guidance to revive the singing and dancing of these ancient songs and dances. A revival of the Northwest culture had spread throughout the villages from Alaska to Washington as carvers and other new Northwest artists studied Bill Holm's *Northwest Coast Indian Art: an Analysis of Form* to recapture an art form that was nearly extinct. Holm photographed and studied the old pieces; some may have even been used in potlatches, of the Tlingit, Haida, Bella Bella, and Tsimshian art that was in museums all over the world. The popularity of Northwest Coastal art is increasing as well as totem pole restoration and replacement in the West Coast communities, such as Queen Charlotte Island in Canada and Prince of Wales Island in Alaska, where they now hold elaborate totem-pole-raising ceremonies and accompanying potlatches. The ceremonies that once lasted a week are now scheduled for 1 to 3 days, usually capping a weekend, thus accommodating the modern villager's work schedule.

The potlatch is a festival tradition that has evolved from the special feast of the humble hunting/gathering tribes of the northwest, to the non-equalitarian tribes structuring castes, to the competitive potlatch wars. The potlatch may continue to evolve and birth new traditions; an example of this is "Celebration," initiated by Sealaska in Juneau. This festival is a celebration of the Tlingit, Haida, and Tsimshian Cultures. Although not a potlatch per se, the potlatch dances and songs, native languages, and art come alive

Photograph by Pamela Rae Huteson

during this burgeoning festival held in Southeast Alaska since 1981. With more Northwest natives seeking to express their culture in ever expanding ways, the potlatch is thriving, and becoming a stronger influence in the lives of the new generations that are here, and those yet to come. "Gunulsh-Cheesh, Hoho" (Tlingit—Thank you, very much)

POTTERY AND CERAMICS

Pottery is clay that has been manipulated into a particular form and heated to harden and maintain its shape and durability. Clay is found on much of the Earth's surface. Depending on the area in which it is found, clay may have many characteristics. Clay may be found finer in texture, smoother and purer in some areas; in other areas the clay may be coarse with several foreign particles. Clay may also be found to be more flexible and pliable in some areas as compared to others. The characteristics and traits of the clay will determine the outcome and quality of the pottery that is produced. Clay is formed from two types of decomposed rock. Primary clay involves decomposed rock found among other rocks from which it originated. Secondary clay is made by decomposed rock, which has been washed down hills by means of waterways, and relocated from its place of origin. The outcomes will be determined by which material is used and in what quantities the ingredients are used as well. In its preparation, three materials are essential for the creation of pottery. Simply put, clay, water, and fuel to fire the objects are the ingredients needed to make pottery. Different types of pottery include materials such as brick, terra cotta, earthenware, stoneware, bone china, and porcelain. Primary clay is used in constructing porcelain, bone china, and earthenware, where as secondary clay is used in forming coarse earthenware and brick.

The Preparation of Pottery

The construction of pottery involves the collection of clay and the addition of water. The clay that is to be

used in the process of pottery making must first be prepared in a specific manner. Foreign objects and particles must be removed from the clay. Next, the potter constructs the form he desires by wedging the clay until it forms into the proper texture and consistency that is needed to form the object. Then it must be evenly proportioned in order to form the object properly. The object usually rests upon a wheel that spins while the potter manipulates the shape, allowing for an even distribution of the clay. This wheel was often referred to as the thrower's wheel or potter's wheel. This technique is used for vessels such as bowls, pots, or other circular objects. The invention of the wheel allowed for more pots to be made in a fraction of the previous time. Before the wheel was discovered, hand building and other techniques were used to manipulate and distribute clay. Clay was pinched, rolled, and pressed to form pots.

Larger pots were created by pressing and scraping together coils or clay rings. Pots were also molded from placing the clay over or inside existing objects such as baskets and or gourds. Pots could also be formed by pinching out clay from large lumps that were found. Once the object is in its correct form, it may be decorated. Incising, scraffito, and color can be added at this time. Afterward, it is left to dry and then plunged into intense heat (a process known as firing). In order for the clay to harden into a durable and hardwearing object, it must be subjected to temperatures above 600°C. Some clay is more resilient to heat and therefore must remain in higher temperatures or longer periods of time. One technique of adding color to clay is the use of chemical reactions caused by heat and metals or minerals such as: cobalt to produce blue, manganese for purple, antimony for yellow, and iron for brick red. Other types of clay may not be able to withstand such intense heat, and therefore need to be covered by a glaze. Glazing is used to create watertight products. Glazes are used for color and design and provide a glossy finish that is easier to clean.

History of Pottery

As archaeologists continue to uncover and find new ancient sites of past civilizations, they continue to discover more information and traces of the technology that were used during that time, such as pottery. Clay is thought to have been developed independently by various cultures throughout history. The history of

pottery begins with the use of clay in prehistoric times around the Indus Valley and Mesopotamia. Pottery may not have been the primary use of clay. Clay was used in relation to magic and religion. Clay figures were created in shapes of humans and animals. These figures symbolized and represented different aspects within a culture. Certain sculpted figures were believed to facilitate the fertility of women. It is also suggested that these clay items could have been used for trade. The earliest forms of pottery were found from Anatolia. Cave dwellers were associated with this society around the Mesolithic period of 6500 B.C. Most of the pottery that was produced was of symbolic figurines, simplistic in design and decoration, and useful and functional objects. Early representation of pottery appears to be underdeveloped due to the lower temperatures used in the firing process. This caused the finished product to be porous and fragile.

The Far East

Areas within the Far East, such as Korea, Indo-China, and Japan, have been greatly influenced by China and the changes that took place within China during the archaic period. Chinese techniques and pottery designs were integrated into neighboring cultures and societies. They developed high temperature kiln-firing techniques. They also created stoneware with high-quality glazes that would later be used in a major step toward the development of porcelain. Eventually they developed white, translucent porcelains superior to those already invented. By the 18th century, with the increase of international trade, Chinese pottery and porcelain were often shaped and decorated to fit the needs of other societies (for example, European populations). The Far East brought significant progress and advancements in the techniques used on pottery and ceramics. These developments and refinements elevated pottery to the level of an art form.

The Middle East

Islamic artisans applied many of the pottery techniques used by Near Eastern potters, such as the production of glazed quartz fritwares and alkaline-based pottery. Arabian mosques and other structures were decorated and built using stucco, colorful mosaics, sculptures, and paintings. These were created with the

aid of artists from Syria, Egypt, Iran, and Mesopotamia. There are three main periods that constitute the history of Islamic pottery: the early period, 9th and 11th centuries, which produced T'ang white porcelains and stonewares; the medieval period, 12th to 14th centuries, with its concentration on Sung white wares; and the later period, 15th to 19th centuries, known for the blue and white wares of Ming China.

Europe

Lead-glaze was quite popular in the production of pottery and ceramics in Europe. Near the end of the 18th century, lead had proven to be quite harmful to health; therefore, its use and production was mostly associated with peasants. Tin-glazed pottery became popular in Europe. It had previously been produced in the ancient Near East and established in Mesopotamia in the 9th century. Tin-glazed pottery gave way to more artistic possibilities due to its dense white surface that allowed the artist to paint more freely upon its surface.

Pottery and the Industrial Age

This period represents a stage where the art and production of ceramics became more complex. The Industrial Revolution brought great influence over Britain's style of pottery. Transfer-printed pottery had begun with pictorial images. There was interest in the Early Victorian style of printed ware and cream wares. Emphasis soon shifted toward the use of scenes (for example, rustic, fantasy) to decorate pottery in the 1830s. Although this trend diminished in the third quarter of the century, decorating pottery with floral designs continued. By the mid-19th century, the production and manufacturing of jugs became popular in England, followed by teapots. Naturalistic scenes began to appear at this time. In France, the development of salt-glazed stoneware began to produce printed patterns. Due to the discovery of color glazes and new technologies, the decorative arts took precedence over sculpture and painting during the early industrial revolution. Classical and Renaissance styles emerged by the mid-19th century.

Pottery in the Modern Day

Heightened interest in the artistic aspect of pottery and ceramics is the result of changes to the process

of pottery making, such as heating pottery in a stable environment and new glazing technologies. A variety of objects have been created from pottery and ceramics by manipulating shapes and colors. Pottery-making and ceramics have been more functional, (e.g., wall tiles for kitchens and bathrooms, sculptures, vases, and everyday items, all expressed in many styles). Ceramic painting and graphics became a focus of the Pop-art movement in the United States in 1960s, particularly with artists Andy Warhol and Robert Indiana. The ancient art of pottery continues to have a profound impact on cultures, inspiring each generation of artists.

PRAGMATISM

Pragmatism is a philosophical school of American origin, generally and internationally acknowledged as a genuine American contribution to the world philosophical heritage (the word “pragmatism” has its origin in the Greek “pragma”—“action,” “affair”). It reflects the broader American social experience and cultural context with its roots in Puritan theology, with Calvinistic ethics of hard work in the precariousness of frontier life, with a desire for success in the New World experiment, with the encouragement of inventiveness, and a practical sense of making the ideal of good life work, and so on, having provided the necessary, though not sufficient, background for emerging such a philosophy. The first tenets of pragmatist thought sprang from seminal discussions of the *Metaphysical Club* in the academic milieu of Cambridge, MA, in the 1870s. This narrow circle of various scholars included polymath Charles Sanders Peirce (1839–1914), psychologist William James (1842–1910), mathematician Chauncey Wright (1830–1875), historian John Fiske (1842–1901), Justice Oliver Wendell Holmes, Jr.

(1841–1935), philosopher Francis Ellingwood Abbot (1836–1903), and Nicholas St. John Green (1830–1876). However, Peirce and James as renowned progenitors of pragmatism were modest enough to mention several non-American predecessors (such as the Greek schools of Sophists and Skeptics, F. Bacon, G. Berkeley, A. Schopenhauer, J. S. Mill, A. Bain, Ch. Darwin, and, notably, I. Kant.), who provided similar ideas and attitudes, such as an evolutionary approach to nature, life, and reason, theory of the practical and inferential nature of knowledge, the purposive character of belief, and the role of will and desire in forming belief. Based on the integration of these concepts, Peirce established the principle of pragmatism in his 1878 paper, “How to Make Our Ideas Clear,” as follows: “Consider what effects, that might conceivably have practical bearings, we conceive the object of our conception to have. Then our conception of these effects is the whole of our conception of the object.” This principle was intended to serve as the method of finding the meaning and testing the truth and value of scientific concepts and theories and as providing an objective criterion for an empirical (experimental and observational) scientific practice (owing to which pragmatism is, improperly, identified with positivism). Twenty years later Peirce’s colleague, James, in a lecture titled “Philosophical Conceptions and Practical Results,” and delivered at the University of California in 1898, modified and subsequently popularized this principle, while crediting Peirce as the father of pragmatism, as follows: “The ultimate test for us of what a truth means is indeed the conduct it dictates or inspires.” Pragmatism, according to James, is not only a “a new name for some old ways of thinking” but much more a “temper of mind, an attitude; it is also a theory of the nature of ideas and truth; and finally, it is a theory about reality.” To this extending of the principle to human practical life and action in general, Peirce reacted with disgust and suggested rather to label his conception as “pragmatism,” a “term ugly enough to be safe from kidnappers.” The move, made by James, had meant for Peirce the departure from objectivity to subjectivity and from science to religion. Whereas Peirce felt it important to find a method of true science, James believed that human happiness was important. James’s project was to show that truth is a much broader concept that extends the lines of science and relates to human life and action not only as an epistemological ideal but also as a practical value and need. Thus, science and

religion are both legitimate endeavors in human life, while both have different purposes. Pragmatism appreciates science but is by no means a scientism. It makes substantial room for human values, ethics, education, and social life. Roughly at the same time, in the late 1890s, John Dewey (1859–1952), who was partially inspired by both Peirce and James and partially influenced by Hegel and Darwin, accomplished definitely the move in the same direction by forming his experimental school at Chicago and formulating his “instrumentalism.” Dewey regarded science as important but only a fraction of the human process of inquiry. He believed that science is being developed and corrected in the name of human happiness. The value of science is subordinated to the values of life, which are of a communal nature. By collaborating with Dewey, the trio of the founding fathers of pragmatism had been completed and the three versions of classical pragmatism formed: scientific/methodological, which incorporates logic and semiotics as the theory of signs and language (Peirce); psychological/humanistic, which incorporates ethic and religious belief (James); and social/political, which incorporates culture and education (Dewey). Thus pragmatism provides and develops the relationship of philosophy to these three important areas: science and knowledge, life and action, community and democracy.

The philosophy of pragmatism in general is multifaceted. However, it can be characterized by several key attitudes. It never has been, nor was it intended to be, a unified doctrine (while critics have accused it, improperly, of eclecticism). Rather it has been searching for the sort of “third” way in philosophy: between materialism and idealism in ontology and rationalism and empiricism in epistemology. This has brought up the pragmatist opposition to traditional theory of knowledge and truth, now labeled as anti-representationalism and anti-foundationalism. The concept of the world in itself for us is not valid; there is just the world as we see it through our needs and goals. Humans, both within and without philosophy, provide the descriptions of the world that suit our intentions one way or another. Therefore, the pragmatist fundamental philosophical intention from the onset has been the “reconstruction in philosophy,” as Dewey called it, directed against the main European streams of thought such as Platonism, Cartesianism, and Kantianism. However, it may best be described, in a sense, as “Anti-Philosophy,” I (i.e., anti-dualism comprising the reworking of all substantial traditional

philosophical oppositions such as subject-object, mind-world, theory-practice, morality-prudence, individual-society, science-religion, etc.) into a coherent and contextual conception formed from the viewpoint of philosophical anthropology based on the sense of, and orientation to, the gradual betterment of human practical life (owing to which interpreters have identified it, falsely, with Marxism). Simply, philosophy should change its topics and orientations in order to be renewed and keep itself alive and relevant within the culture. Because the platonic quests for absolutes, certainty and eternal principles are as self-deceptive as futile; philosophy should be the critical public discourse aimed at, as Dewey stated, solving the “problems of men and women” and, as Rorty added, an edifying conversation.

Pragmatism is an open, anti-dogmatic, pluralistic, and practice-oriented philosophy (while critics have accused it, improperly again, of typically American success-oriented and pay-off doctrine). The idea that the practical consequences pay (owing to which interpreters have identified it, falsely again, with utilitarianism) has become the pragmatist standard for evaluating the truth, meaning, and value—these are taken as equivalent to the practical, empirical consequences derivable from them and should be judged according to what they mean practically for humans and their lives. By “practical,” pragmatism does not understand the “bread and butter” consequences, but the empirical, experiential, particular, and concrete, and includes also such considerations as logical consistency, intellectual satisfaction, and harmony of mental content. If these do not affect human life, experience, and action, they are supposed to bear only a very restricted and dubious meaning. The idea “works,” if its consequences fulfill our expectations and goals, i.e., if it brings satisfaction to us. The function of the mental (thought, inquiry, experience) is not theoretical but practical—it consists not in providing knowledge as such, but knowledge, thought, and feeling as a presupposition to better action. Pragmatism has emphasized the “plastic” nature of reality and the practical function of knowledge as an instrument for adapting to reality and controlling it. Pragmatism stresses live, dynamic experience over fixed principles. To think as a pragmatist is to consider the consequences, to imagine the definite differences that follow from each alternative, and to decide in that way which of the two “works” better. The alternative, which works better, is true.

The most contested aspect of pragmatist philosophy has been its conception of truth. In opposition to traditional epistemologies, which take truth as a representation of reality in our cognition “as it is in itself” and regard it as an epistemic goal “for itself,” the pragmatist approach to truth is Darwinian, or “functional,” or “instrumentalist.” Truth is a non-epistemological, practical value, and a means rather than an end. First, it is highly dubious that humans have a privileged capacity to attain such a representation of reality that corresponds to it as a true copy; second, humans make use of their representations of reality they dub as truth—and even of all representations—in order to achieve their practical ends. The human mind works in a truly Darwinian mode: it is permanently providing the selections of all representations of its content so that it is able to select those that can best serve all various kinds of purposes that human beings can pursue. Such a selection is naturally fallible and corrigible; as such, the concept of a truth that is applicable to all kinds of human condition and situation cannot be. Thus there is no static truth, much less absolute truth; there are truths, and these are constantly being made true. There are no necessary truths or axioms; there are only postulates. Truth has no metaphysical or transcendental essence; it is fully the outcome of human inquiry, which includes both thought and experience, and is a critical, self-corrective social process. There is no other warrant of truth apart from this inquiry.

The significance of pragmatist philosophy for anthropology in particular can be seen to consist in several specific ways of answering the question: “What does it mean to be human?” First, being human is regarded as the self-image of humanity based on naturalism, evolutionism, and holism. By taking Darwinism seriously, pragmatism asserts the continuity of nature with culture, of natural and cultural evolution in the sense that humans practice the same as animals do, only in a different way and on a different level. Even if the purposes of both kinds of evolution are the same, to adapt to environment, humans maintain their lives via thought and intelligent action. Even such a unique phenomenon as human language is primarily a tool for coping with the world and coordinating human action. Due to this, human adaptations are much more dynamic and creative in comparison to all other nature. Humans adapt nature to their needs rather than simply adapting to it. The limits of human adaptive/transformational

power seem to be almost unrestricted; the pragmatist conception of “meliorism” stems from this power (i.e., the idea that humans are able to cope, despite the fact that it is sometimes difficult, with the problems of their existence). It is also the self-image of humanity based on socio-cultural constructionism. Certain human creations have not and could not have pre-existed culture and society, (e.g., according to James and Dewey this is the human *self*). Human power is self-transformational and via creating culture we create ourselves. Individual and social developments cannot be in any way separated from each other. The task, however, is not only to attempt self-creation of an individual, but at the same time attempt creation of a democratic and communicative cultural community. The creation of such a community means the most we humans can accomplish; it is the creation of our truly intelligent and social home environment. However, the creation of such a community is not to be taken as “the goal of human history.” It is the result of our free choice rather than of any kind of inner or outer necessity, and it can be achieved only thanks to our intelligent efforts. This amounts to the assertion that there hardly can be such concepts as the universal and stable human nature. From the broadest ethical and political points of view, humans are bequeathed to ourselves, and we are the only agents responsible for what we have, and shall become. There is no other authority residing above us to direct our human evolution and destiny. Humanity must form its values and decide to act on behalf of them. Thus, if we are to speak of any kind of “human nature,” according to pragmatism, this should consist in the intelligent and democratic creation of opportunities for better human action and satisfaction in life.

The pragmatist school has exerted influence, which has shown its peak in the first two decades of the 20th century even across the border of the United States, and is impacting the fields of law, education, political and social theory, art, and religion. Apart from resolute critics such as B. Russell and G. E. Moore from Cambridge, England, one of the most original followers of pragmatist thought is Oxford’s Ferdinand C. S. Schiller (1864–1937), who titled his own version of pragmatism “humanism.” Pragmatist philosophy had also been spread over such countries as France and Italy and even China and Japan, with protagonists including Ch. Renouvier, H. Poincaré, M. Blondel, É. Le Roy, H. Bergson, G. Papini, G. Vailati, and M. Calderoni. However, with the demise of both James

and Peirce, the movement slowed a gradual decline, and it was Dewey who had remained its almost single recognized spokesman in the first half of the 20th century. On the American side it was replaced by logical positivism and analytic philosophy of language. Nonetheless, it can be proved that pragmatism has never completely faded out and in American universities there always have been academics representing it (for example, J. Royce, C. S. Morris, C. I. Lewis, S. Hook). In the 1950s even the leading logical positivists such as Rudolph Carnap (1891–1970) and Willard V. O. Quine (1908–2000) started to recognize pragmatism's importance, which has been featured in their own doctrines. Similarly, the progenitor of analytic philosophy, Ludwig Wittgenstein (1889–1953), in the whole later stage of his career had espoused ideas and attitudes similar to those of pragmatism. Thus the soil could have been prepared during the 1960s and 1970s for the “pragmatist turn” in Western philosophy, strongly inaugurated by Richard Rorty (1931–) with his salvo in *Philosophy and the Mirror of Nature* (1979) and later confirmed in *The Consequences of Pragmatism* (1982) and other writings. This revived version of pragmatism (neo-pragmatism) has also been enriched by some influences of Nietzsche, Wittgenstein, Heidegger, Gadamer, Sartre, and Derrida. Thus, toward the turn of the millennia, we have witnessed the resurgence of pragmatism represented not only by Rortian “post-analytic neo-pragmatists,” but also by many versions of “neoclassical pragmatism,” such as “Neo-Percean,” “Neo-Jamesian,” and “Neo-Deweyan” associated with the whole range of contemporary American philosophers. Moreover, pragmatism has become a broader international philosophical movement, which includes, apart from such important figures as Jurgen Habermas (1929–) and Karl-Otto Apel (1922), many more followers and students worldwide.

PREHISTORY

The earliest period of world human history, which is often regarded also as constituent part of cultural and/or social anthropology, prehistory is aimed at reconstruction of world diversity of forms, and ways of human being's and human society's development since their origin until the formation of early political structures. The perspective purpose of prehistoric studies is the detection of general and particular regularities in anthropological, social, ethnic, economic, and mental evolution of humankind at the early stages of its existence.

The subject field of prehistory in its contemporary comprehension covers series of global theoretic issues; among them:

- problem of genus Homo and modern human beings' origins and physical anthropological evolution;
- formation of human community, family, kinship, and sociality;
- rise of ideology, mythology, arts, speech, and rational knowledge;
- origin and evolution of production, livelihood systems, household activities, economic systems, products distribution, exchange, and property;

shaping of self-identification in different forms, ethnic and gender including:

formation of leadership, hierarchy, power, and administration;

origin of private property, exploitation, and classes.

Chronology and periodization. Prehistory appears to be the longest period of human history, which covers approximately 5 million years. Chronological frameworks of prehistory traditionally are referred with special events in social history and are considered relative as far as the irregularity of social progress of humankind, which displays itself already at this earliest stage of human history.

The beginning of prehistory could be referred with the origin of the earliest representatives of genus *Homo*, which currently is dated between 5–2 million years B.P. in Africa, approximately 1 million years ago in Europe and Asia, an estimated 40,000 years B.P. in Australia, and even less in America.

Formation of the earliest states in the Near East and Egypt (border of 4,000–3,000 years B.C.) traditionally is regarded as the upper frame of prehistory in its world global context. At the same time in Europe and America the prehistoric phase of human history lasts over first millennium A.D., and in particular, in the communities of Africa, Australia, and America, the prehistoric phase is still in progress.

Three main epochs could be distinguished in the frameworks of the prehistoric period of human society, body, and cultural evolution:

- period of anthroposociogenesis (i.e., time of formation of *Homo sapiens* and human society);
- period of primitive community, or epoch of classic prehistory, with its two phases: phase of Early Prehistoric Society (hunter-gatherers community), and phase of Late Prehistoric Community (time of early farmers and cattle-breeders);
- period of formation of political structures (states), private property, and exploitation.

Source base. Unlike other fields of historical knowledge, prehistory has no primary written sources for its reconstruction as far as it has to deal with the pre-literary period of human society. The source base of prehistory consists of data of many natural and humanitarian sciences, which gives the possibility to learn about the human body, human activity, society, and the natural environment, in which prehistoric

processes, events, and phenomena occur. Most fruitful among these sciences are archaeology, ethnography, and physical anthropology. Additional information about early phases of human history could be provided by primatology, paleontology, paleogeography, geology, palinology, archaeobotanic, archaeozoology, palaeoclimatology, petrology, genetics, linguistics, art criticism, sociology, demography, physics, chemistry, statistics, information technology, mathematics, and others providing scientific data and the peculiar methods and approaches of their processes. As a result prehistory tends to be an interdisciplinary synthetic field of historic and anthropological knowledge whose reliability and cognitive potential deeply depend on the complexity of the source base used in a particular case study, and on the diversity of approaches and methods that were explored during this source base evaluation and interpretation.

History of prehistoric studies. Traditionally the beginning of prehistoric societies studies is referred with the middle of the 19th century, when early evolutionists in biology (Charles Darwin), cultural anthropology (L.H. Morgan, E.B. Tylor), and other fields of knowledge put forward a necessity to revise traditional creationists' postulates about the place of human beings and human society in the Universe. First attempts of knowledge generalization regarding a pre-state period of human history have been made during the second half of the 19th to the beginning of 20th century.

The first half of the 20th century has become the period of database intensive accumulation. The necessity of its theoretical conceptualization has caused the origin of a wide spectrum of approaches, directions, and schools of prehistoric studies. Ideas of cultural anthropology, ethnography, and sociology created grounds of diffusionistic, functional, cultural, sociological, structural, and Marxist interpretations of prehistoric processes and phenomena.

Deep integration of prehistoric studies with natural sciences (geography, biology, climatology, etc.) at the second half of the 20th century has caused specific ecological interpretation of prehistoric culture, livelihood systems, and productive activity in Western Europe, the United States, and the Soviet Union.

The formation of a post-industrial society from the end of the 20th to the beginning of the 21st century has caused the propagation of postmodern forms of prehistory comprehension as image or text.

In West European understanding, prehistory sometimes is contrasted to proto-history, which concentrates on prehistoric communities studies on the basis of written sources of neighboring civilizations.

Significance of prehistory in contemporary world. Today prehistoric reconstruction seems to be acute with regard to the general theoretic comprehension of many processes and phenomena that occur in the contemporary world. At the border of the third millennium, postsocialist societies face the process of private property and economic hierarchy formation; traditional societies of Central Africa as well as communities of inner parts of Southern America experience social inequality, power struggle, and the shaping of political administration. Our knowledge about the peculiarities of these processes' realizations many thousands of years ago could help us to model and settle many problems that inevitably arise in this context.

Existence at the beginning of the 21st century of many societies whose culture, livelihood systems, and mode of life correspond to hunter-gatherers or early farmers and cattle-breeders' phases of historical evolution causes the deep moral significance of prehistory. It helps to comprehend the uniqueness of these contemporary prehistoric societies, evaluate their importance for our past understanding, realize their potential for further inner development, and exclude racial, cultural, moral, or other types of discrimination.

Theoretical conceptualization of many global philosophic issues (for example, the origin of human beings and the sense of their lives on Earth, the genesis of ideology and its historical evolution, the appearance of art, the formation of different forms of identification and self-realization, the origin of sociality and culture, the development of speech) shapes the worldview and philosophic significance of prehistory as special field of knowledge.

PRIMATE BEHAVIORAL ECOLOGY

Taxonomy

Primates belong to the order Primates. Members of this order include prosimians, monkeys, apes, and humans.

The primates are divided into two suborders: Prosimii and Anthropoidea. Prosimians are the more primitive members of our order, i.e., they more closely resemble the earliest primates, whereas members of Anthropoidea (i.e., monkeys, apes, and humans) are more derived, that is, they exhibit evolved characteristics not present in the ancestral primates.

Geographic Range

The majority of primates are found within 20 degrees north and south latitude of the equator. They primarily inhabit the continents and surrounding islands of Africa, Asia, and South America. One species of monkey, the Barbary macaque, is native to Gibraltar; however, it is believed to have been introduced by the Romans and, in modern times, restocked by the English. Primates, while largely confined to the tropics, also inhabit more temperate regions.

Primate Habitats

Forest-Living Primates

Forests can be divided and categorized according to their stage of development and/or regeneration (e.g., primary forest, secondary forest, forest edge, disturbed areas). While primates have specific habitat requirements, some species' requirements are more stringent than others. For example, those species that locomote via brachiation (i.e., swinging by their arms) typically require primary forest. Other species are more adaptable and can inhabit a variety of forest types and possibly even disturbed areas. In the area of Costa Rica where I conduct research on howler monkey-feeding ecology, spider monkeys are found only in areas where the forest is continuous. Howler monkeys, conversely, can be seen in trees alongside roads in beach communities and traveling along electrical wires. Other species that do well in disturbed areas include species of langurs, macaques, and marmosets.

Tropical Forest

Most of the world's primates inhabit tropical forests. Primarily, forest-dwelling species are arboreal in nature. Tropical forests can be classified by the amount of rainfall they receive, ranging from rain forests to dry forests. Rain forests experience little seasonal variability and rain falls year round. There is high species diversity but low species density. Thus, in a given unit of land, for example, many tree species

will be present but at low numbers. Tropical forests that are not categorized as rain forests exhibit a greater degree of seasonal variability, in having both wet and dry seasons, and have lower species diversity but higher species density.

Primates are, to varying degrees, insectivorous and/or herbivorous. The degree of seasonality in a given area thus affects what is available as food at any point in time, since the life cycles of many insect and plant species are correlated with climatic conditions. Even in rain forests, where conditions are more stable, plant production cycles and the patchy nature of food resources affect food abundance and availability for primates.

Tropical forests contain a variety of habitats where primates are found. Some species have very specific habitat requirements. For example, Allen's swamp monkey inhabits swamp forests of central Africa; proboscis monkeys are found adjacent to water on the island of Borneo; mountain gorillas inhabit cloud forest areas of central Africa; and certain genera of sakis and uakaris are found only in the seasonally flooded Amazonian forests.

Temperate Forest

There are several genera of primates that are found in temperate regions (e.g., areas of China, Japan, India, and Argentina). A few species are even found in high altitude/latitude areas where it snows seasonally. Several species of macaques live in regions that experience relatively high amounts of snow (for example, the snow monkeys of Japan, the Tibetan macaques of China, and the rhesus macaques of northern India). The Yunnan snub-nosed monkeys (genus: *Pygathrix*) of the Himalayan Mountains of China endure the coldest temperatures and longest winters of any non-human primate. At certain times of the year, their diet consists primarily of hanging lichens.

Mixed Woodland

Primates found in more open areas tend to be semiterrestrial quadrupeds, for the obvious reason that the forest is not continuous. Several species of primates inhabit open woodland/scrub areas of sub-Saharan Africa (for example, savanna baboons, vervet monkeys, patas monkeys, and chimps). Some of these species are also found in more heavily forested regions, e.g., baboons and chimps. Two of these open-habitat species (the baboons and patas monkeys) exhibit cursory adaptations due to the greater risk

of predation in an open environment. While most species sleep in trees, baboons in open, dry areas sleep in large congregations on "sleeping" cliffs.

Dry Environments

Two species of primate live in very dry habitats. The Hamadryas baboons inhabit the dry plains of Ethiopia, the driest habitat of any nonhuman primate. Gelada baboons are also grassland animals of Ethiopia. They are found on the high Ethiopian plateaus. They are adapted to eating a diet that consists, primarily, of grass. They creep along in a sitting position, picking grass blades, seeds, and corms. Both of these species rely on cliffs and gorges for sleeping sites.

Home Range

Primate species vary in the size of the home range they occupy. For example the smallest of the primates, the mouse lemurs, are reported to have home ranges as small as 50 meters in diameter, whereas chimps can have home ranges of up to 40 kilometers. This variability is due to body and group size or to diet. Small animals tend not to range as far, and hence have smaller home ranges as compared with larger animals. Solitary foragers may not have to range as far as group-living primates because they do not have to compete with other group members for access to food. Finally, the dietary pattern of a species affects how large a supplying area, or home range, it needs. Thus, when comparing two group-living species that ingest a high quantity of leaves (which are relatively more abundant than fruit), gorillas with their larger body size would need larger home ranges than howler monkeys. When comparing ripe fruit specialists with more folivorous species, it is apparent that due to the patchy nature of fruit sources, the more frugivorous species need larger home ranges. Chimps and spider monkeys are considered to be ripe fruit specialists. They are closely related to gorillas and howler monkeys, respectively. Chimps have much larger home ranges than do gorillas, and, likewise, spider monkeys have much larger home ranges than howler monkeys. In the dry forest in Costa Rica, a spider monkey group's home range includes howler monkeys' home range as well as multiple other howler groups' home ranges.

Some species defend their home range from conspecifics (i.e., other members of their species) and are thus termed territorial. They actively ward off

intruders, either individuals or groups of conspecifics, from their home range and especially from their core area. The core area is that area of a group's home range that is used and defended more intensively. Even those species that are considered to be nonterritorial will often defend their core area, whereas there may be a degree of overlap with surrounding groups of conspecifics in more peripheral areas of their home range.

While the distance traveled in a day, termed day range or daily path length, is often correlated with home range size, it is variable, and it too is often related to diet. Once again, those species that ingest a relatively higher percentage of fruit in their diet tend to range farther in search of fruit. For example, chimps can range up to 15 kilometers in a day. In addition, both chimps and spider monkeys fission into smaller foraging parties to avoid competing with other group members for this highly ephemeral resource.

Activity Cycles

Many researchers have recorded data on how primate species spend their time during the day and night as engaged in the following activity categories:

Feed: time spent actively engaged in feeding and foraging activities.

Rest: time spent resting during the day or, in the case of nocturnal species, at night.

Move: time spent moving through the home range.

Social: time spent engaged in social activities with family/group members (for example, grooming, playing, sexual behavior).

Species vary in the amount of time they spend in these various activities. In addition, activity cycles may vary both within and between seasons. For example, some species spend more time moving during the wet versus the dry season. Likewise, during the wet season, when rain is intense, or during the dry season, when sun and heat are intense, animals may move less. During the six-month dry season at one Costa Rican study site, the howler monkeys ranged from 7 to 10 hours resting time per day in 11 hours of observation. As you can imagine, this varies considerably from usual human patterns.

Diet, social organization, and group size and composition influence activity cycles. Because primate species can be categorized by their diet as well as type

of social organization, and, to a lesser extent, by group size and composition, species tend to exhibit less within-species variability than between-species variability in activity cycles. Thus, activity cycles can be thought of as characterizing a species or being species-specific. Howler monkey activity cycles are thus skewed toward resting and less so toward social activity. My study group spent less than 1% of its time engaged in social activities. Conversely, the rhesus macaques I observed on the island of Cayo Santiago, Puerto Rico, were highly social and spent much less time resting than my howler subjects.

Research demonstrates the role that reproductive condition plays in female rhesus macaque activity cycles on the island of Cayo Santiago, Puerto Rico. The time that females spent in the various activity categories did not differ before or after an infant was born. However, as the infant increased in size, lactational demands increased to the point that females were spending almost no time resting or involved in social activities. This is especially surprising because subjects were provisioned, meaning that they were supplied with food. They supplemented their intake of monkey chow with plant parts. As the infants began to feed on their own, the females spent less time feeding/moving and more time in rest and social activities.

Feeding Ecology

The following general definitions pertain to dietary categories that are relevant to the primates:

Herbivory: consumption of plant matter. The following are sub-categories of herbivory:

Frugivory: consumption of fruits.

Folivory: consumption of leaves.

Gramnivory: consumption of grass.

Nectivory: consumption of nectar.

Gumnivory: consumption of plant exudates (for example, sap, latex).

Faunivory: consumption of animal matter. The following is a sub-category of faunivory:

Insectivory: consumption of insects.

Omnivory: consumption of a combination of plant and animal matter.

Source: © iStockphoto/Kevin Tate.

All but one species of primate (the tarsier) are herbivorous to some degree. Most species consume fruit for carbohydrates, with the remainder of the diet made up of either leaves or insects to fill their protein requirements. Smaller primates usually consume a combination of fruits and insects (*frugivore-insectivores*), whereas larger species usually consume a combination of fruit, flowers, and leaves (*frugivore-folivores*). This size differential is due to the fact that large animals are not able to meet their dietary needs by foraging for insects. This is not to say that larger animals never consume insects. The largest primates—chimps, orangs, and some gorillas—consume tiny ants and termites.

Some of the primates are relatively unique in terms of their diet and foraging strategies. The tarsier is the only extant primate that is completely faunivorous, ingesting a variety of insects and small animals (for example, snakes, birds). The smallest of the New World monkeys (i.e., the marmosets and tamarins) are partly gummivorous. These animals have modified nails that resemble claws. They are used to cling to upright trunks/branches to consume exudates. The marmosets have specialized front teeth that are used for gouging holes in trees to access exudates. Exudates are a very important aspect of their diet, and they defend those trees that are used for their consumption from neighboring monkey groups. The tamarins do not rely as extensively on exudates, and they lack the dental specializations seen in the marmosets. Some of the Madagascar lemurs are nectivorous and serve as important pollination agents. Bamboo lemurs feed primarily on bamboo shoots, which

contain cyanogenic compounds that are highly toxic to most mammals. The gelada is the only primate that is considered to be graminivorous, with as much as 90% of their diet coming from grass consumption. They occupy the high treeless plains of Ethiopia. While several species of primate are known to hunt small- to medium-sized mammals (for example, capuchins, baboons, orangutans, and chimps), only the chimps are known to hunt cooperatively. However, Strum observed her savanna baboon subjects to change their hunting strategy to more of a relay style, so that when one male was

tiring, another male would take up the chase. This is the only non-chimp case that I know of that suggests a modicum of cooperation.

As mentioned, most primates consume fruit to varying degrees. In general, these fruits are ripe. However, some species can consume unripe fruit, and thus avoid competition with other species. I have often observed howler monkey subjects feeding in fig trees (figs are a preferred fruit of primates) for 1 week or more before the other two resident species (spider and capuchin monkeys) began to feed on them.

Because primate olfactory capabilities are reduced relative to other mammals, there is speculation that some groups of primates have derived visual capabilities for detecting when fruit is ripe. All of the Old World anthropoid primates possess trichromatic color vision, which allows us to distinguish the red-green hues of the spectrum. Two species of New World monkeys—the howler and capuchin monkeys—also possess this adaptation, but it evolved independently from the Old World species. All of the remaining species possess dichromatic vision. An alternate hypothesis to the ripe fruit scenario is that trichromacy may have evolved in response to leaf consumption. Young leaves are preferred over mature leaves in most species of primates. They are higher in water and lower in structural carbohydrates, and, in some cases, may be higher in protein and lower in chemical defenses. Some plant species produce red pigments, termed anthocyanins, in their young leaves. These anthocyanins act to “disguise” the leaves from those animals possessing dichromatic vision because they perceive them as being dark and hence mature.

Trichromatic individuals can discern the color red and can possibly even be attracted to the leaves or at least be able to “see past” the red streaking and detect the underlying yellow-green color that is characteristic of young leaves.

While the majority of larger primates are frugivore-folivores that prefer fruit to leaves, the degree to which they depend on fruit varies. As mentioned, some species are ripe fruit specialists and they range far and wide in their search for fruit sources. Alternatively, though, are those species that rely on leaves to a greater extent, especially when fruit is unavailable. Three groups of primates exhibit this strategy: (1) members of the Old World monkey subfamily Colobinae, (2) gorillas, and (3) two species of New World monkeys, the howler monkeys and the muriquis. The Colobinae (i.e., the colobus monkeys of Africa and the langurs and leaf monkeys of Asia), have specialized stomachs for digesting leaves. The microflora in their foregut are capable of breaking down a larger proportion of the plant structural carbohydrates, hemicellulose and cellulose, relative to the other large anthropoid primates. This is termed foregut fermentation. They can thus derive energy from this more ubiquitous food source. The other two groups—the gorillas and the two species of New World monkeys—are hindgut fermenters. They lack the gastrointestinal specializations seen in the colobines but are still capable of deriving energy from leaves via an elongated large intestine and slower throughput time (i.e., the time food takes to pass through the gut). These primate groups minimize energy expenditure because their gut activities are costly and leaves are a poorer source of energy relative to fruit.

Social Organization in Relation to Ecology

Social organization refers to the grouping patterns and inherent “rules” that determine group membership and conduct in social animals. Before a discussion of social organization can be attempted, however, several terms need to be clarified. There are several mating patterns that are relevant to primate social organization. They are as follows:

Monogamy: an individual having only one mate, often for life.

Serial monogamy: an individual having only one mate at a time. This is the mating pattern seen in humans and will not be discussed herein.

Promiscuous: an individual with multiple mating partners, especially females during a single estrus period.

Polygamy: an individual having more than one mate, regardless of the sex of the individual.

Polygyny: a male with more than one mate.

Polyandry: a female with more than one mate.

In addition, there are relevant membership patterns, especially those involved with who comes and goes within groups. They are:

Natal group: group into which an individual is born.

Female-philopatric: females stay in their natal group, also termed matrilineal.

Male-philopatric: males stay in their natal group, also termed patrilineal.

Emigration: an individual leaves its group, natal or otherwise.

Immigration: an individual enters a new group.

Solitary Foragers

There are several genera of primates that are categorized as solitary foragers. For the most part, these animals are small nocturnal foragers that rely on crypsis (camouflage) to avoid detection by animal prey and predators (for example, the nocturnal prosimians of the families), Cheirogaleidae (mouse and dwarf lemurs), Galagonidae (galagos or bush babies), and Loridae (pottos and lorises). Females leave their young in nests or park them on branches while they are out foraging. Some of the Loridae have evolved a unique form of locomotion, termed slow climbing, that allows them to move very slowly and freeze for long periods of time so as to avoid detection.

In the past, these animals were categorized as having a solitary social organization wherein the largest grouping consisted of a female and her dependent young. Males and females came together for mating purposes. However, as more research has been conducted with these species, it has become apparent that their social organization is more complex. In many cases, it is now realized that male home ranges are large, relative to females', and they overlap multiple female home ranges. This discovery has prompted a revised category of social organization for these species, termed *dispersed polygyny* since the male has

multiple mates. In addition, females may house their young communally in tree holes or leaf tangles (for example, mouse lemurs), and these females may be related, i.e., matrilineal (for example, galagos).

The exception to the solitary forager as nocturnal frugivore-insectivore is the case of the orangutan. While oranges are also an example of dispersed polygyny, it is not nocturnal insectivory that prompts their solitary ways, but rather that they are large arboreal frugivore-folivores that need a lot of food to satisfy their needs. Females cannot “afford” to share their home ranges with other females. They do depend on the resident polygynous male to protect them from non-resident males (often sub-adults) that may attempt to “rape” them. Orangs are the only nonhuman primates wherein rape has been reported. It is thought that forced copulation is a strategy whereby males may sire offspring before acquiring a home range and females of their own. It can thus be seen that this is a good example of an evolutionarily stable strategy that could have been selected for. Resident males respond to female screams and chase these “unwanted” males away.

Monogamy

Monogamy is seen in three primate families (Indriidae, Tarsiidae, Hylobatidae) and three genera of Atelidae (owl, titi, and saki monkeys). In addition, one species of the Colobinae, the Mentawai leaf monkey, is monogamous. This type of mating pattern is also termed “territorial pair,” in that bonded pairs defend their home ranges from other conspecifics. Because there is no male-male competition for females once pairs have become established, monogamous species are monomorphic (i.e., males and females do not differ in morphology, especially size). It is an exceptional type of mating pattern because male mammals are not reproductively limited as are females. It is thus a bit of a conundrum how this mating pattern could have been selected for since natural selection works to maximize reproductive success. There are, however, ecological characteristics that correlate with monogamy and hence are used to explain its occurrence. They are (1) the nature of the resource base, i.e., patchy distribution in time and space, and (2) the need for resource defense from conspecifics. These factors necessitate the partner's cooperation in home range defense. Thus a lone female cannot be expected to defend a suitable supplying area to guarantee the successful rearing of her young.

Those males that cooperated with females to defend resources and raise young had a reproductive advantage given these environmental constraints and, thus, the trait(s) was/were selected.

Two genera—the indris (genus: *Indri*) and the gibbons and siamangs (genus: *Hylobates*)—practice duetting to aid in territorial defense. This involves the male and female “singing” coordinated duets to demonstrate to surrounding conspecifics that the home range is under bonded pair occupation. This behavior is believed to have evolved as a spacing mechanism, relieving pairs from constantly having to monitor all areas of their home range. In at least one species of primates—the owl monkey—pairs do not exhibit overt bonding behaviors of duetting and grooming. Yet, they are truly monogamous in that they do not practice extra-pair copulations whereas, for example, gibbons and siamangs do opportunistically mate with outside conspecifics.

Polyandry

Only one subfamily of primate—the Callitrichinae (i.e., tamarins and marmosets)—exhibits this extremely rare form of social organization. As with monogamy, it does not make adaptive sense for a male to limit his reproductive success by staying with, or in this case, sharing one female. Once again, however, there are extenuating circumstances that make this form of social organization adaptive for these primates. In addition, it may not always be the case that two males are sharing a female but rather that one male is “bidding his time” awaiting the opportunity to mate with the resident female. In these species, the norm is for the female to birth twins. The newborns can weigh up to 24% of the female's weight. The males are primarily responsible for carrying and caring for the twins. Independent offspring may also help care for their young siblings. The female's primary role is nursing the offspring and she spends much of her time foraging to fulfill lactational demands. It is usually the case that only the dominant female breeds in the majority of these species due to reproductive suppression of subordinate females. The mechanism by which this occurs is either through pheromonal production by the dominant female or aggression toward the subordinates resulting in them being anovulatory, i.e., they do not ovulate.

Garber has shown that those groups with two resident males are more likely to successfully rear both offspring, thus demonstrating the adaptive

significance of the “helper male” phenomenon. It is thought that a male (heretofore referred to as the primary male) mates with the female and that the other male (secondary male) is demonstrating his alloparental (care given to offspring by someone other than the parents) skills in the hopes that the female will mate with him when the primary male leaves. Transfer between groups is common in these species. Thus, the secondary male can move into position as the breeding male when the primary male leaves. Of interest is the fact that male hormone profiles change when they are actively caring for infants. They exhibit higher levels of prolactin, which is implicated as having a key role in maternal behavior.

One-Male–Multi-Female

Traditionally, this type of social system was referred to as a harem, implying that one male had control over a group of females. Once again, however, as more research has been conducted with free-ranging groups of primates, the picture has changed. Only one species of primate exhibits a true harem social organization. The basic unit of *Hamadryas* baboon social organization is a male and his small group of females. The male maintains control of his females by herding and punishing them for straying, especially if they move too close to other males. The other species that live in one-male groups do not have the same degree of male control over the females, and the male's tenure in the group is often of short duration. For example, in the gelada baboon, the male relies on the support of the females in order to remain in residence. If an outside male attempts to take over the group, he may very well do so if the resident females do not ally with the current male. In the case of the patas monkeys, the resident male does not even have exclusive reproductive rights to the resident females. During the mating season, outsider males mate with some of the females. While this seems not to be in the male's best interest, the resident male, on average, impregnates a higher percentage of resident females than outsider males, and it is possible that those males that are associated with a group of females have differential access to resources such as food and water relative to bachelor males.

While some species of primates exhibiting this type of social organization are matrilineal (for example, *Hanuman* langurs), others, such as gorillas, are not. In addition, because male tenure may be short due to

male takeovers, infanticide by the new males is seen in some species. This practice is interpreted as an evolutionarily stable strategy on the part of the males. Relative to females, males have a much lower probability of reproducing. Their options are limited because not all males are successful in acquiring a group of females and, as mentioned, tenure in a group is short due to the constant pressure from outside males. When a nursing infant dies, the mother ceases to lactate and becomes sexually receptive (i.e., “in estrus”). By killing off dependent offspring, the male has a greater probability of passing on his genes. While it may seem strange that a female would mate with a male that has killed her infant, it may be in her best interest, reproductively speaking. First, it would not be adaptive to delay becoming pregnant again. Second, if infanticide is under genetic control, a female may increase her own reproductive fitness by producing infanticidal sons that will have a better chance of reproducing.

The one-male grouping pattern is believed to have evolved where the resource base is insufficient to support larger groupings. In effect, females' reproductive success would suffer beyond a given threshold of individuals.

Multi-Male–Multi-Female

Many species of New and Old World monkeys are multi-male, as are some of the lemurs of the Madagascar. There is a tendency for multi-male groups to be matrilineal. It is theorized that where resources are defensible, females have evolved the pattern whereby they remain in their natal group and cooperate with kin (i.e., matrilineal). With regard to spider monkeys and chimps, the males remain in their natal group and defend an area; this attracts females emigrating from other groups and is termed resource defense polygyny. Because both of these species are ripe fruit specialists and fruit is patchy in time and space, the group fissions into small foraging parties. While the group is comprised of multiple males and females and, hence, multi-male–multi-female, these species are categorized as having a fission-fusion or community type of social organization because of their unique pattern of intermittently fissioning and later, reuniting. In the case of the chimps, the core of the group is composed of groups of related males. These males actively defend the home range. Within this home range, females inhabit smaller individual home ranges. Thus it can

be seen how the term community is appropriate for this species.

PRIMATE EXTINCTION

Several causative factors contribute to the drastic reduction of primate populations in the world. The major contributors are the destruction of habitat due to deforestation, the illegal pet trade, and the bushmeat trade: all due to the expansion of humans into primate habitat.

The overpopulation of the Earth by *Homo sapiens* is the dominant force driving primate extinction. The world population in 2004 was estimated at 6,390,147,200 individuals. The United Nations (U.N.) projects a lower fertility rate and increased mortality risks due to HIV/AIDS for the global community. During the next 47 years, the population of the world is conservatively expected to increase by 2.6 billion people. According to the 2002 U.N. population estimates, if fertility were to remain constant in all countries at current levels, the global population could more than double by 2050, reaching 12.8 billion.

The human population is increasing with momentum; our increasing population's survival needs will place escalating strain on the Earth's natural resources.

The human race depends on the Earth's natural resources to sustain itself. Food, income, fuel, water, shelter, medicine, and electricity are obtained from the environment. When local human populations deplete nearby resources, the populations must expand outward to fulfill their survival needs. With the creation of roads, dams, and infrastructure intended to support the human race, the expansion weakens the environment. This development takes thriving forests and grasslands and renders them environmentally unproductive, resulting in an increase in resource utilization and further perpetuating the cycle of unsustainable development. It is estimated that approximately 1% of the world's remaining tropical forests, and 0.4% of the Earth's total forests, are being destroyed every year.

Roads and other man-made infrastructure impact primates by modifying their behavior and species distribution. Primates are impacted directly by the noise, movement, and destruction of the physical environment caused by humans. Primates tend to avoid the fragmented and developed areas created by humans. The disappearance of ancestral habitat, and degradation of existing habitat, results in the reduction of primate breeding success, and overall decreases in primate populations.

Although world food production is still increasing, human population growth is beginning to overwhelm farmers' production ability. The reduction in undernourished people is still only 27% of the goals set by the U.N. More than 800 million people were undernourished in the year 2000. The explosion of the human species places an ever-increasing strain on the food resources supplied by the environment that sustains humankind.

In Africa, as in many parts of the world, the growth of the logging industry has facilitated access to the forest. Alternatively, increasing urban populations are heightening the need for food sources. The result is an explosion in the trade of bushmeat: forest animals killed for sale as food. This trade provides a relatively quick income to people living in an area with few options for income generation. Hunters remove more than 1 million metric tons of bushmeat from the Congo Basin forests each year. The rising demand for bushmeat, the opening of old-growth forests, the lack of alternative options for income generation, the absence of protein substitutes, and the lack of capacity to enforce existing laws, are the driving factors that threaten primate conservation across West and Central Africa.

If current trends continue, primate extinction on a global level will be a grim reality, one in which the only way left to experience primates will be at zoos and in laboratory settings.

PRIMATE CONSERVATION

Presently between 33% and 50% of all primate species are endangered. Primates by definition are the most highly developed order of mammals and include humans, apes, lemurs, and monkeys. Over 100 species of primates are either threatened or endangered, mainly due to loss of tropical forest habitat.

Conserving primates is a difficult job for several reasons. First, most primates live in Third-World countries. People in these nations have trouble just eking out an existence, and there is little money available for conservation of animals. Another factor is the low reproductive rate of primates. For example, chimpanzees only have one baby every 5 to 6 years, and 50% of baby chimps die during their first 2 years. This means it takes a long time to build up the population.

Over the years, many of the primates have been killed. Bonobos and cebids have been hunted for food. Rugs are made for tourists from the skins of the black and white colobus. Farmers shoot primates that raid their crops. Baboons and macaques are especially known as crop raiders. Some primates are caught in traps set for other species including deer.

Primates, being similar to humans, are captured and used in medical research. Chimps are used for AIDS research, and research with rhesus monkeys led to the discovery of different blood types.

Some primates are caught and sold as pets. Apes are popular pets in parts of Asia. When baby animals are captured and sold as pets, the mother is typically killed. Nearly 90% of captured baby primates die during transport.

Habitat destruction is another serious problem that endangers primates. Tropical forests are disappearing quickly, and this is a prime habitat for many primates. Logging has made big inroads into the rain forest, as wood is needed for heat and cooking. Trees are being destroyed to make room for planting crops. What can be done to save primates? The Convention on International Trade in Endangered Species (CITES) agreement was signed by most countries in the 1970s. It limits trade in endangered species, both for the pet trade and for medical research. This has reduced the number of primates being captured.

Habitat destruction is a more difficult problem to solve. Much of the solution lies in educating people about habitat conservation. Organizations such as Primate Conservation, Inc. work to protect primate species.

— Pat McCarthy

PRIMATE EXTINCTION

Scientists fear that the extinction of one species of monkey may herald the beginning of an "extinction spasm." The Miss Waldron's red colobus monkey was declared extinct in 2000, making it the first extinction of a primate since the late 1700s. Scientists believe it won't be the last this century, though.

The red colobus monkey, discovered in 1933 by naturalist Willoughby Lowe, was named after his companion on that trip, Miss F. Waldron. The monkey has not been seen in its natural habitat in Ghana and the Ivory Coast since 1978. In 1993,

suspecting that the monkey might be extinct, scientists launched a series of searches through the area on the west coast of Africa. A 6-year survey of 19 different forested areas ensued and local residents were interviewed; however, scientists were unable to find a trace of the primate. Because the monkey was large, colorful, and noisy, and had a distinctive loud call, it seems reasonable to conclude there were none in the area. The researchers also consulted hunters, park rangers, and forest department personnel, before declaring the monkey extinct.

The fact that its habitat covered such a restricted area probably contributed to the animal's extinction. Heavy hunting contributed to the loss of the colobus monkey, as did loss of habitat. Over 90% of West Africa's original rain forest has been destroyed, mostly by logging. The red colobus monkey was extremely sensitive to habitat alteration and could only survive in a high canopy forest. Scientists who attempted to breed the monkeys in captivity were unsuccessful. They were also unable to replicate the monkey's diet.

Because of loss of rain forest habitat, other primate extinctions can be expected during the next century. Studies have shown that animals can become extinct up to 100 years after a forest is destroyed. Rain forest loss is expected to proceed at a high rate. Scientists predict that by 2040, West Africa will lose 70% of its remaining forests. The scientists who conducted the search for the colobus monkey noted that other large monkeys were also becoming rare in the area.

It is possible to save the primates in the area, but doing so requires much education and cooperation. Poaching is a big problem, and the park rangers are poorly equipped, trained, and supervised. There are too few rangers to deal with the armed hunters. Educating locals about ecology and appreciation of their natural heritage is a long-term goal. Another problem is the human population growth. For example, the population of Ghana is expected to double within the next 20 years, which will lead to a greater loss of habitat. Scientists believe programs to limit population growth are also crucial to the survival of primates in the area.

— Pat McCarthy

PRIMATE LOCOMOTION

Primate locomotor habits can be divided into several major categories, each characterized by different patterns of limb use and body positions. These categories are quadrupedal running and climbing, vertical clinging and leaping, arm suspension, and bipedal walking. A primate chiefly uses one of the four types, but may use other types at least some of the time. Primate locomotor characteristics evolved in small quadrupedal mammals with a body weight of less than 100 grams. Contrary to other tree-living small mammals, such as squirrels or tree shrews, primate ancestors inhabited the small branches of the forest canopy, where the diameters of supporting branches are often smaller than the diameter of the animal's trunk. The evolution of prehensile autopodia, combined with the use of a diagonal foot-fall pattern, provides stability and balance on such unstable supports.

Primates walk along branches with flexed limbs to keep the trunk close to the support. Thus, primates are able to avoid strong vertical oscillations of the trunk by accommodating to uneven substrates. Independent of their anatomical length differences, the fore- and hind limbs undergo equal angular excursions, and their proximal pivots are on the same level. The longer hind limbs are much more flexed than the shorter forelimbs; this allows the animal to accelerate immediately powered by the hind limbs without losing time in flexing the joints.

Arboreal quadrupedalism is the ancestral and most common locomotor mode among primates, and it was the basis for the evolution of specialized locomotor behaviors (for example, slow climbing, terrestrial quadrupedalism, and arm suspension).

Slow quadrupedal walking and climbing is a distinctive mode of quadrupedalism in the Loridae family (lorises and pottos). Members of this group are known for their rather stereotypical, stealthy locomotor behavior, practiced in any direction in space, on the branch or underneath. Loridae do not leap or perform any other fast gait, but they use large step lengths produced by great limb angular excursions. They have a very powerful grasp, because their first digits are more abducted against the other digits. The high oxidative capacity of their limb muscles enables these primates to hold tightly to a branch for hours without fatigue.

Unlike arboreal quadrupeds, the locomotive apparatus of Old World cercopithecine monkeys shows functional and morphological adaptations to terrestrial running on broad, flat surfaces. These adaptations are seen even in secondary arboreal cercopithecine monkeys. Old World monkeys have a narrow, deep trunk, and parasagittally oriented, more-extended limbs. The fore- and hind-limb length of terrestrial quadruped monkeys is nearly identical.

Primates of all sizes can cross gaps in the three-dimensional meshwork of their arboreal habitat by leaping. The necessary speed for take-off is attained by a rapid extension of the hind limbs from a deep crouched posture. Larger primates gain additional momentum by swinging their long arms. At the end of the leap, primates use their strong, long hind limbs as shock absorbers during the landing.

Vertical clinging and leaping is a highly specialized type of leaping between vertical supports. Vertical clingers and leapers are members of the prosimian families Galagidae, Tarsiidae, Indriidae, and Lepilemuridae. Because they are performed backwards, leaps between vertical supports are more complex than those between horizontal supports. From a clinging-squatted position on a vertical trunk, the thrust of the feet launches the body up in the air, with a rotatory momentum that twists the trunk around its longitudinal axis. The animal rotates to face the target in a symmetrical position. Then, a rotation around the transverse axis shifts the feet to a position suitable for landing. Tarsiers and galagines use their tails to correct their rotatory momentum during the flight phase.

Many primates can hang below arboreal supports by various combinations of arm and leg support. A more specialized mode of suspensory locomotion is brachiation. Brachiation represents slow to moderate pendular arm swinging, where the trunk undergoes rotation under the supporting forelimb. It differs from ricochet brachiation by the speed and by the absence of an aerial phase. Brachiation is used in its most stereotypical and finest style by hylobatids and atelines. Atelines frequently use their prehensile tail to maintain an additional hold when they brachiate. Brachiating primates have long forelimbs. Their trunks are relatively short and have a broad thorax with a short lumbar region. The shoulder joint has the greatest range of movement of the whole

locomotor apparatus. The thorax of apes and atelines is broad, and the scapula has been repositioned dorsally changing the orientation of the glenoid fossa to a more lateral and cranial position. Redirection of the glenoid sockets increases the span of the arms and their range of circumduction. Brachiation and arm suspension in the stem lineage of the Hominoidea explain many of the morphological peculiarities of the upper limb and thorax shared by living apes and humans.

Great apes are generally capable of vertical and horizontal climbing and suspensory arm swinging as well as quadrupedal fist or knuckle walking, and bipedalism. Knuckle walking is a type of terrestrial quadrupedalism, which is unique to the African great apes pan and gorilla. The knuckles are used to carry the weight of the upper body.

Human beings are the only primate species that habitually walk bipedally. Human beings walk with a fairly extended knee and hip joint. They use their legs in a pendular-like fashion in contrast to the spring-like manner of quadruped mammals. Additionally, human bipedality differs from the facultative bipedality of apes in the systematic use of a torsional twisting of the trunk, and the contralateral symmetry of leg- and arm-swinging.

Vertical climbing is considered to be a biomechanical link between brachiation and bipedalism. To date, this hypothesis is the most popular and generally accepted explanation of humans' evolution to bipedalism. However, shared features of the wrist in African apes and humans, features which are functionally related to stabilizing the wrist during knuckle-walking, support the idea of a terrestrial quadrupedal phase in hominid evolution.

PRIMATE MORPHOLOGY AND EVOLUTION

Taxonomy

Primates belong to the order primates. Members of this order include prosimians, monkeys, apes, and humans. The primates are divided into two suborders, Prosimii and Anthropoidea. Prosimians are the more primitive members of our order (i.e., they more closely resemble the earliest primates), whereas members of Anthropoidea (i.e., monkeys [New and Old World], apes, and humans) are more derived, that is, they exhibit evolved characteristics not present in the ancestral primates.

Evolutionary Trends

Primates are distinguished from other mammals by a variety of physical and life history characteristics, termed evolutionary trends. The term “trend” is used because they are either 1) not present in all species (for example, the lack of an opposable thumb in prosimians and New World monkeys) or 2) vary in the degree to which they are present (for example, prosimians retain a claw on the second digit of their feet and have smaller brains and shorter developmental periods as compared with higher primates).

Primate Evolutionary Trends

- Relatively large complex brain, especially cerebral cortex.
- Decreased reliance on olfaction and corresponding reduction of snout and brain area associated with smell.
- Increased reliance on vision and corresponding enlarged visual cortex and adaptations that increase visual acuity and color and depth perception.
- Generalized diet and dentition.
- Tendency toward upright posture.
- Prehensile (grasping) hands and feet with opposability (big toe and thumb can touch other digits of foot and hand, respectively).
- Nails instead of claws.
- Increase in efficiency of placental nourishment to developing fetus.
- Long pre- and postnatal periods with greater reliance on learning.
- Tendency toward diurnality.

Primate Groups

Prosimians vs. Anthropoid Primates

Prosimians exhibit skeletal characteristics that distinguish them from anthropoid primates. Two joints of the craniofacial region differ between prosimian and anthropoid primates. When growth ceases in anthropoids, the mandibular symphysis (midline lower jaw joint) and the frontal suture (midline forehead joint) fuse. In prosimians, these joints remain open throughout life. The prosimian dental formula, that is, the numbers of the various types of teeth (for example, incisors, canines, premolars, molars) in each half of each of the jaws differs from all but some of the New World monkeys, in that they have an extra premolar. Thus, they have 36 rather than 32 teeth. They exhibit procumbent, or forward-oriented, lower incisors. They use this “dental comb” to comb through and groom their fur. The retention of a claw on the second digit of the feet of most species also serves a grooming function. Anthropoid primates are distinguished by the presence of extra bone in the back of the eye sockets/orbits so that their eyes are encased in bone. Prosimians lack this postorbital closure.

Prosimian Characteristics

Unfused metopic suture and mandibular symphysis.

Dental formula 2–1–3–3.

Dental comb.

Grooming claw.

Lack of postorbital closure.

Nocturnality with corresponding visual adaptations: enlarged eyes with rite mirabile.

Greater dependence on hearing and mobile external ear flaps.

Greater reliance on olfaction: relatively long muzzle with moist rhinarium.

Upper lip is split and fused to the upper jaw.

Lack of facial musculature result in inexpressive face.

Digits act together (powerful grip).

Tendency toward vertical clinging and leaping as locomotor pattern.

Multiple births and corresponding pairs of teats.

Most of the extant prosimians are nocturnal and, with the exception of the tarsier, which is intermediate in many physical characteristics between the prosimians and anthropoids, they possess an adaptation for increased visual acuity in low light conditions, termed a *tapetum lucidum*. They have relatively more acute auditory abilities as well, and have mobile external ear flaps, as seen in other mammals. They also rely on olfaction more than most anthropoid primates and, thus, retain the primitive mammalian characteristic of a moist fleshy pad (rhinarium) at the tip of their relatively elongated muzzle. They practice scent marking and possess scent glands on various parts of their body. Their upper lip is split and fused and they lack the facial musculature seen in the higher primates, resulting in a lack of facial expression capabilities.

Prosimians, as well as New World monkeys, lack opposable thumbs and, therefore, lack the degree of manual dexterity seen in the Old World anthropoid primates. Prosimian digits instead act together, giving them a powerful grip. They have a tendency to locomote by a pattern termed vertical clinging and leaping (see “Locomotor Categories”).

There is a tendency among the prosimians for multiple births per birthing event, and thus most species have multiple pairs of teats. Within the anthropoid primates, the norm is for single births (except for the New World tamarin and marmoset monkeys) and two teats.

New World Monkeys

New World monkeys are characterized by a suite of characteristics. Of interest is the fact that tail prehensility evolved independently in the atelids and the capuchins. Squirrel monkeys, which are closely related to capuchin monkeys, have prehensile tails only in infancy.

New World Monkey Characteristics

All species:

- Arboreal.
- Platyrrhine nasal morphology (i.e., rounded and laterally placed nostrils vs. Catarrhine nasal morphology, which consists of narrow, downward-oriented nostrils as seen in the Old World monkeys and apes).
- Long tails in most species.

Callitrichines: tamarins and marmosets:

- Dental formula 2-1-3-2 (all other species have 2-1-3-3 formula).
- Modified claw-like nails on all digits except big toe (which has a nail).
- Twins are the norm.

Some atelids (for example, spider monkeys, howler monkeys, muriquis, and woolly monkeys) as well as capuchins have prehensile tails.

One species, the owl monkey, is secondarily nocturnal, meaning that it is derived from a diurnal ancestor.

Old World Monkeys

The Old World monkeys also have several characteristics that distinguish them from the other anthropoid primates. There are important differences between the two sub-families of Old World monkeys. The members of the subfamily, cercopithecinae, are commonly referred to as the cheek-pouch monkeys. These monkeys have a cavity inside their cheeks wherein they temporarily store food. It is hypothesized that once they encounter a food source, they can quickly stuff their cheek pouches and mouths and move to a safe location to chew and eat. This could be potentially important in the case of semiterrestrial species encountering food on the ground whereby they might avoid predators and/or conspecifics (i.e., members of their own species). Enzymatic digestion also begins in these pouches. The colobinae are also distinguished by a dietary-related adaptation. Colobines have complex sacculated stomachs and benefit from foregut fermentation processes. Stomach microflora separate the structural components of plant material, particularly leaf cell walls. The process yields volatile fatty acids that provide energy to the animals. Thus, colobine monkeys can ingest comparatively large amounts of leaf matter relative to the other anthropoid primates. In addition, they have higher capabilities for breaking down the secondary compounds plants produce as deterrents to animals and microorganisms (for example, fungi). Additional differences between the two subfamilies can be seen in the following list.

Old World Monkey Characteristics

Tendency for arboreality but a relatively large number of species are semi-terrestrial.

Larger body and brain size, in general.

- Tendency for ischial callosities (i.e., bare-calloused sitting pads).
- Sexual swellings in many species.

Characteristics That Distinguish the Two Subfamilies of Old World Monkeys

Colobinae	Cercopithecinae
Complex stomachs	Cheek pouches
High folivory	High frugivory and omnivory
Dental specializations for leaf consumption	More generalized dentition
Primarily arboreal	Arboreal and semi-terrestrial species
Elongated hind limbs with good leaping abilities	Limbs more equal in length
Long tails	Variable tail length

Apes

Apes are distinguished by a suite of characteristics related to their ability to hang and swing by their arms, termed a suspensory hanging adaptation (see “Locomotor Categories”). Various aspects of their shoulder girdle, upper limb, and hand morphology reflect this capability. In addition, they have relatively larger brains and longer life stages relative to the other primates. The apes are divided based upon their body size into the small bodied “lesser apes” (gibbons and siamangs) and the larger bodied “great apes” (gorillas, oranges, and chimps). Except for the gorillas, the other species of apes are opportunistic omnivores, and their dentition reflects this fact. The lesser apes are monomorphic, that is, the sexes do not differ in size or morphology (except for genitalia). This is related to the fact that they have a monogamous social organization. The great apes, in contrast, are sexually dimorphic. This is taken to the extreme in the gorillas and oranges. Extreme sexual dimorphism is related to male-male competition for mates. The male gorillas and oranges defend their females from infanticidal and “raping” males respectively. The pronounced “fighting teeth” seen in male apes are also the result of male-male competition, but certainly also serve the chimps in their hunting activities.

Primate Evolution

The first primates are believed to have evolved during the Paleocene epoch (i.e., more than 55 million years

ago). These early primates were likely descended from small nocturnal insectivorous mammals. The tree shrew is commonly viewed as an extant model for what these earliest primates or primate predecessors would have been like. The earliest fossil primates are from North America and Europe. They are divided into two super-families, adapoidea and omomyoidea. In general, the adapoids were lemur-like diurnal frugivores with some insectivory and folivory likely, whereas the omomyoids were small nocturnal insectivore-frugivores. It was during the Eocene epoch (~55–35 million years ago) that these early prosimians speciated on a grand scale, termed an adaptive radiation, expanding into numerous niches over a wide geographic area. They spread into Asia and mainland Africa. The ancestors of the Madagascar primates are believed to have rafted from the mainland on floating mats of vegetation. Eventually, due to global cooling, the ancestral primates of North America and Europe became extinct.

By the late Eocene, the first anthropoid primates had evolved and remains are found in Africa and possibly Asia. The richest location for early anthropoid fossils is the Fayum Beds of Egypt.

These ancestors of the monkeys and apes are believed to have descended from an omomyoid ancestry but there are numerous debates on the subject. It was during the oligocene epoch (~23–35 million years ago) that the anthropoid primates experienced a great adaptive radiation. Oligocene anthropoids are divided into three families, parapithecidae, oligopithecidae, and propliopithecidae. The New World monkeys are believed to have descended from the most primitive of the early anthropoids, the parapithecids. New World monkeys are more primitive than their Old World counterparts, and they share some characteristics seen in the Parapithecidae. How the ancestors of the New World monkeys migrated to the New World is unknown, but, once again, a rafting hypothesis is proposed. There is no evidence of a North American origin for New World monkeys as there have been no discoveries of anthropoid fossils. In addition, even if anthropoid primates evolved in parallel in the Old and New Worlds, the ancestral New World monkeys would still have had to raft from North to South America because their appearance in South America precedes a land bridge between the two continents. Thus, the most parsimonious explanation is an Old World origin.

The ancestors of the Old World monkeys and the apes branched off from the family propliopithecidae, during the oligocene. *Aegyptopithecus zeuxis* is believed by some to be a possible propliopithecid contender for a member of the ape lineage and possibly the Old World monkey lineage as well. While the earliest anthropoids were more monkey- than ape-like, it is the apes (or hominoids) that were the first to successfully adapt to changing environmental conditions in Africa. It is during the Miocene epoch (~23–25 million years ago) that the adaptive radiation of the hominoids can be observed in the fossil record. There were approximately 20 genera evident during the Miocene. This is surprising considering that there are only four nonhuman genera today. These early apes exhibited a wide range of body size (3.5–50 kilograms) and foraging strategies. While the ancestry of the lesser apes (gibbons and siamangs) is difficult, the extant great apes can be traced to the genus *Proconsul* at approximately 18 million years ago. After that point, the ancestors of the orangutans, genus: *Sivapithecus*, left Africa and moved into western Asia. Apes also moved from Africa into Europe. It is difficult to trace the origins of humans and the modern African apes during the mid-Miocene as there are many conflicting viewpoints. However, suffice it to say that the ancestry of the hominids (i.e., the bipedal primates) branched off during this time and, along with the Old World monkeys, experienced an adaptive radiation into the Pliocene (1.6–5 million years ago) and Pleistocene (10,000 to 1.6 million years ago) epochs. In response to the success of the anthropoid lineage in Africa and Asia, the only surviving members of the suborder Prosimii in those areas are nocturnal. A nocturnal niche allowed them to survive alongside the larger and more cognitively superior anthropoid primates in that they could avoid competition for resources.

Locomotor Categories

While primates (1) exhibit a generalized skeleton, (2) are capable of locomoting using a variety of means, and (3) can, essentially, walk bipedally for at least short periods of time, they tend to habitually practice one form of locomotion and can, thus, be categorized as such. Primate skeletons exhibit some specializations to their particular mode of locomotion. The locomotor categories seen in the primates are slow climbing, vertical clinging and leaping,

arboreal quadrupedalism (also termed branch-running), semi-terrestrial quadrupedalism (also termed ground-running), brachiation, knuckle walking, and fist walking.

Slow Climbers

The only species that practice this form of locomotion are the pottos and the slow loris. These animals are solitary nocturnal foragers that rely on crypsis, or camouflage, to avoid detection by predators and prey. They are drab in color, move slowly through the trees, and can freeze in place for long periods of time due to a vascular specialization in their extremities, termed “rite mirabile.” They lift one limb at a time and move forward in a slow mechanical fashion. They can also move on the underside of branches.

Vertical Clingers and Leapers

The earliest primates are believed to have practiced this mode of locomotion based upon fossilized skeletal evidence. It is, thus, not surprising that many of the living prosimians are either categorized as vertical clingers and leapers (VCLs) or have the capability to do so. VCL involves leaping from a vertical substrate by powerfully extending the elongated hind limbs, arcing up and out, and landing on another vertical substrate, usually feet first. The most specialized of the VCLs are the tarsier. Galagos/bush-babies and the indriids (indris, avahis, and sifakas) are also primarily VCLs. Many other species are capable of VCL in varying degrees (for example, most of the remaining Madagascar prosimians as well as the tamarins and marmosets of the New World). Due to their elongated legs, the true VCLs hop or gallop when on the ground.

Arboreal Quadrupeds/Branch-Runners

The majority of primates are arboreal quadrupeds. All of the New World monkeys are categorized as such, along with the majority of Old World monkeys and many species of prosimians. The name of this locomotor category reflects the activity, e.g., walking/running through the trees, on a variety of substrates. Arboreal quadrupeds tend to have longer legs than arms and, thus, have good leaping capabilities.

Semi-Terrestrial Quadrupeds/Ground-Runners

All but one species of Old World monkeys (the Hanuman langurs of Asia) are members of the subfamily cercopithecinae (the cheek pouch monkeys).

Several species of Old World monkeys (the baboon, patas, vervet, certain guenon and mangabey monkeys of Africa, and the macaques, predominately of Asia) spend much of their time on the ground and are, thus, categorized as semi-terrestrial quadrupeds. Their arms tend to be longer than their legs, and the general morphology of their shoulder and hip regions more closely resembles other terrestrial mammals (for example, cats and dogs). Some species have specialized adaptations for speed, termed cursorial adaptations. The baboons, and especially the patas monkeys, can run very fast. They walk/run on the tips of their digits and have relatively long limbs. Macaques walk on the palms of their hands and, accordingly, most species spend much of their time in trees.

Brachiators

Brachiation is a unique mode of locomotion that involves swinging by the arms on the underside of branches. One hand grasps onto a branch, pulling the body forward, and the other hand then reaches out for the next branch. Two groups of primates have evolved the ability to brachiate, independently of one another—the apes and spider monkeys. All of the apes (including ourselves) exhibit what is termed a “suspensory hanging adaptation.” This adaptation involves a very mobile shoulder girdle that allows a 360-degree range of motion. Thus, we can hang and swing by our arms and hands.

The lesser apes such as gibbons and siamangs are sometimes known as “true” brachiators due to their enhanced brachiating capabilities that are the result of a suite of derived characteristics, relative to the other apes. Their trunks are shorter, their arms and fingers are longer, and their thumbs are reduced so that their hands resemble hooks. They swing fluidly through the forest, but must walk or run on the ground with their arms in the air, due to their length. Brachiating is not the primary mode of locomotion in the great apes, and they are not as adept. Adults are seldom observed to brachiate due to their large size, but young animals are often seen to hang and swing by their arms, especially when playing.

Spider monkeys are sometimes referred to as “semibrachiators” due to the incorporation of their prehensile tails when brachiating. Like the rest of the New World monkeys, they are also fully capable of traveling along branches quadrupedally and leaping between trees.

Knuckle- and Fist-Walkers

The primary mode of locomotion for chimps and gorillas is walking on the knuckles of their hands and the soles of their feet. The middle phalanges (finger bones) are placed flat on the ground and the metacarpo-phalangeal joints (joint between the metacarpals [bones of the body of the hand] and the first phalanges) are hyper-extended. Orangs, in contrast, ball up their hands into fists when they locomote quadrupedally. When in the trees, however, they use their hands and feet to climb through the branches. This is referred to as quadrumanous, or four-handed, locomotion. In order to move from tree to tree, they often use their weight to sway/bend the tree until it is closer to another tree. Male orangs are so large that they often have to drop down to the ground to move from place to place. Male gorillas are primarily terrestrial due to their large size.

PRIMATE TAXONOMY

The Animal Kingdom is divided into 25 to 30 major groups called phyla (singular, phylum): the Arthropoda (insects and spiders), Mollusca, Coelenterata (sea “anemones and jellyfish”), Echinodermata (starfish and sea urchins), and many other phyla that most people would recognize only as “worms.” The phyla are divided into subordinate groups called Classes,

the classes again into subordinate groups called Orders, the orders into Families, the families into Genera (singular, genus), the genera into Species. Within each category, subordinate categories can be inserted: thus, families can be divided into subfamilies where needed (another way of looking at this is to say that the genera of a family can be grouped into subfamilies). Super-families (groups of closely related families) can also be instituted. With finer and finer divisions we may well “run out of ranks,” and unranked groups are perfectly feasible, provided it is widely understood where they belong in the main classification.

The phylum to which Primates belong is called Chordata (crudely speaking, animals with backbones). The phylum Chordata is divided into approximately eight classes, one of them being Mammalia—the mammals, distinguished by having hair and mammary glands. The 20 or so orders of mammals include Carnivora (cats and dogs), Proboscidea (elephants), Chiroptera (bats)—and Primates.

The living groups of Primates are lemurs, lorises, tarsiers, New World (i.e., American) monkeys, Old World (i.e., African and Asian) monkeys, apes, and humans. Linnaeus, the originator of biological taxonomy, in 1758, did not adopt the rank of Family, but divided the order Primates directly into four genera: *Homo* (humans), *Simia* (apes and monkeys), *Lemur*, and *Vespertilio* (the latter being bats—Linnaeus’s successors expelled bats from the Primates). Although he thus separated humans from apes, it is very noteworthy that he did classify humans as Primates; unfortunately most of his successors removed humans and, instead of Primates, recognized two different orders—Bimana (humans) and Quadrumana (other Primates). It was not until a century later that the order Primates was definitively re-instituted (by Mivart, in 1863).

For nearly another century there was dispute regarding what should be the major subdivisions of the order Primates. Most authors tended to regard tarsiers as being related to lemurs and lorises, but Pocock, in 1918, showed that they have more in common with monkeys, apes, and humans, and divided the Primates into suborders Strepsirhini (lemurs and lorises) and Haplorhini (tarsiers, monkeys, apes, and humans). A few taxonomists adopted his classification, but most adopted the one formalized by Simpson in 1945, in which the suborders were Prosimii (lemurs, lorises and tarsiers) and Anthropoidea (monkeys, apes, and humans).

The reason why this matters is because these two competing schemes reflect different philosophies

of what the function of taxonomy actually is. The tarsier shares with lemurs and lorises characteristics such as a small brain—a primitive retention from the common ancestor of all Primates. This certainly makes it look superficially more like a lemur than like a monkey—but it has never been clear why it should be important to classify animals together simply because, in certain selected characters, they are “primitive.” Since the 1960s, the tendency has been more and more to classify animals together because they share an exclusive common ancestor (phylogenetic systematics: originating with Hennig in 1952, and especially with the translation into English of his book *Phylogenetic Systematics* in 1966). It is now clear to most primatologists that the tarsier shares a common ancestor with monkeys, apes, and humans that is more recent than the one they all shared with lemurs and lorises—hence Pocock’s classification is now overwhelmingly preferred.

A still more important example of a change in a prevailing taxonomic scheme is how great apes (orangutan, gorilla, and chimpanzee) are classified. In most of the 20th century the great apes were classified as the family Pongidae, while humans alone were placed in a different family, Hominidae. As the phylogeny became clearer, starting with Goodman’s 1963 immunological work, and the philosophy of phylogenetic systematics spread, doubts began to be expressed about the correctness of recognizing the family Pongidae. It was the orangutan, not humans, whose ancestor separated first among the great ape and human group, so it should be the orangutan that should be classified separately. The growing tendency now is to recognize only a single family, Hominidae, with two subfamilies: Ponginae for the orangutan, and Homininae for gorilla, chimpanzee, and human.

This illustrates one of the ways in which new thinking has gradually been pervading taxonomy. A family is a monophyletic group (descended from an exclusive common ancestor), but why is this group to be ranked as a family, rather than, say, a super-family, or a subfamily, or a genus? Why would we want to recognize a separate family (Hylobatidae) for the lesser apes or gibbons, rather than incorporating them, too, in the Hominidae? Within the Hylobatidae, should we recognize just one genus (*Hylobates*) or four (one each for the concolor, siamang, hoolock, and lar-group gibbons)? There is no consistent thinking about this, but in 1977 Goodman and colleagues proposed that taxonomic rank should be dependant on time depth: a genus should have separated from its closest relatives at least

by the Miocene-Pliocene boundary, and a family should have diverged at least by the Oligocene-Miocene boundary. There is no agreement about this yet, but it is approximately consistent with customary usage.

The Biggest Question of All: What Is a Species?

In 1963 Simpson noted that a species is a unit that evolves separately from others and has “its own evolutionary role and tendencies.” There are different ways in which taxonomists have tried to represent this important insight operationally.

In the 1940s Dobzhansky and Mayr formulated the Biological Species Concept (BSC): species are reproductively isolated from each other. This is often misunderstood to mean that two different species are incapable of interbreeding, or that, if they do interbreed, their hybrids are sterile. Actually, as Mayr insisted time and again, it means that they do not normally interbreed in the wild. (Among Primates, baboons and macaques interbred to give fertile hybrids in captivity; it would be meaningless to classify them all as one species.) It is interesting that, 20 years before Simpson, these authors were already attempting to express an aspect of his evolutionary conception.

There are many reasons why the BSC is not universally applicable. Perhaps the most cogent one is that many species are allopatric to (geographically isolated from) each other, so the question of reproductive isolation is simply inapplicable. An increasing number of taxonomists therefore feel that a more objective, falsifiable, and repeatable criterion must be adopted, and the use of the Phylogenetic Species Concept (PSC), first articulated by Cracraft in 1983, is now widely accepted. Under this concept, a species is a diagnosable entity, meaning that it has fixed heritable differences from other species. The nearest thing to a textbook in the field, Groves's *Primate Taxonomy* (2001), adopted this concept and, under it, recognized over 300 living species of Primates.

An outline classification of living Primates, down to genus level, is shown in the following outline:

Order Primates
Suborder Strepsirrhini
 Infraorder Lemuriformes
 Family Cheirogaleidae

 Subfamily Cheirogaleinae
 Cheirogaleus
 Microcebus
 Mirza
 Allocebus
 Subfamily Phanerinae
 Phaner
Family Lemuridae
 Lemur
 Haplemur
 Prolemur
 Eulemur
 Varecia
Family Lepilemuridae
 Lepilemur
Family Indridae
 Indri
 Propithecus
 Avahi
Infraorder Chiromyiformes
 Family Daubentoniidae
 Daubentonia
Infraorder Lorisiformes
 Family Lorisidae
 Subfamily Lorisinae
 Loris
 Nycticebus
 Subfamily Arctocebininae
 Arctocebus
 Perodicticus
 Pseudopotto
Family Galagidae
 Galago
 Euoticus
 Galagoides
 Sciurocheirus
 Otolemur
Suborder Haplorrhini
 Infraorder Tarsiiformes
 Family Tarsiidae
 Tarsius
 Infraorder Simiiformes
 Platyrrhini
 Family Cebidae
 Subfamily Cebinae
 Cebus
 Subfamily Saimiriinae
 Saimiri
 Subfamily Callitrichinae
 Callithrix

	<i>Callimico</i>
	<i>Leontopithecus</i>
	<i>Saguinus</i>
Family Aotidae	
	<i>Aotus</i>
Family Pitheciidae	
Subfamily Pitheciinae	
	<i>Pithecia</i>
	<i>Chiropotes</i>
	<i>Cacajao</i>
Subfamily Callicebinae	
	<i>Callicebus</i>
Family Atelidae	
Subfamily Atelinae	
	<i>Ateles</i>
	<i>Lagothrix</i>
	<i>Brachyteles</i>
	<i>Oreonax</i>
Subfamily Alouattinae	
	<i>Alouatta</i>

	<i>Procolobus</i>
	<i>Piliocolobus</i>
Tribe Presbytini	
	<i>Presbytis</i>
	<i>Trachypithecus</i>
	<i>Semnopithecus</i>
	<i>Nasalis</i>
	<i>Simias</i>
	<i>Pygathrix</i>
	<i>Rhinopithecus</i>

Superfamily Hominoidea

Family Hylobatidae

Hylobates
Symphalangus
Hoolock
Nomascus

Family Hominidae

Subfamily Ponginae

Pongo

Subfamily Homininae

Homo

Pan

Gorilla

Fossil taxa can be slotted into this scheme where they are required. In the Homininae, there are several fossil genera that are closely related to *Homo*: *Australopithecus*, *Paranthropus*, *Kenyanthropus*, and *Ardipithecus*. If they are valid, this would require that the three genera of Homininae each be given its own tribe (Gorillini, Panini, Hominini), and the other fossils would then be inserted into the Hominini alongside *Homo*. An isolated fossil genus, sister to a whole suborder or family, can be placed, unranked, as a “plesion” of that group.

Notice several distinctions about the classification. First, a few of the old names have been modified: Strepsirrhini rather than Strepsirhini (because it conforms better to the Greek from which it is derived). Notice, too, the use of several standard endings: -oidea for super-families, -idea for families, -inae for subfamilies, -ini for tribes (if even finer division is wanted, subtribes, with the ending -ina, can be inserted below tribes). These are standard throughout the animal kingdom. Suborders, infraorders, and so on have no standard endings (though they are, nonetheless, given them within most orders). Notice, too, that they all begin with an uppercase; and, finally, that generic names are written in italics.

A classification should not be thought of as a “given”; it is a scientific hypothesis, like any other, and should be expected to change as further evidence accumulates.

Species, finally, have two names. First is the name of the genus, followed by the name special to that species: *Homo sapiens*, *Pan troglodytes*, *Pan paniscus*, *Saimiri sciurea*, *Saimiri boliviensis*, *Saimiri oerstedii*. The specific name always begins with a lowercase letter, even though it denotes a country (Bolivia) or a person (Örsted). Also, if subspecies are needed (in completely differentiated geographic segments of a species), a third word is added on at the end (for

example, *Saimiri sciurea sciurea* [the squirrel monkey that occurs in the region where squirrel monkeys were first discovered], *Saimiri sciurea cassiquiarensis* [the squirrel monkey from the Rio Cassiquiare]).

If handled properly, a classification reveals the following: first, it clarifies what the species are (the units), and second, it explains what the monophyletic groups (clades) are; in other words, it tracks the course of evolution. It is still disputed whether it should also to give the reader an idea of the timing of separation of two groups (i.e., what makes a well-thought-out classification an indispensable basis for all other studies in primatology: ecology, behavior, conservation, biogeography, genetics, and pharmacology).

— Colin Groves

PRIMATES, QUADRUPEDALISM

The study of locomotor adaptations is fundamental to the study of primate evolution and ecology. The primates are particularly interesting because they manifest a remarkable diversity of locomotor styles. While workers have often focused on masticatory morphology, data on patterns of locomotion also provide information on the niches occupied by recent and fossil species. While some other mammalian orders contain arboreal, semiterrestrial, and terrestrial representatives, few show the diversity of locomotor modes that are exhibited in the primates. Arboreal primates include various types of quadrupeds, brachiators, “quadrumanus” climbers, and vertical clingers and leapers. Terrestrial primates include quadrupedal forms and the unique striding bipedal hominins.

While considerable attention has been devoted to the unique and spectacular forms of primate locomotion, such as brachiation and vertical clinging and leaping, the most common locomotor mode received comparatively little attention until recently. Most primate species are quadrupedal, and the quadrupedal species often bridge the gap between locomotion on the ground and in the arboreal milieu. The assumption that all primate quadrupeds are basically the same in their anatomy and behavior is inaccurate because of both phylogenetic and ecological considerations. In a phylogenetic sense, quadrupeds are represented in a variety of infraorders, including Lemuriformes, Chiromyiformes, Loriformes, and Simiiformes. Within

the Simiiformes, the Platyrrhini include clawed forms and other species with prehensile tails. In contrast, there are no known catarrhines with either claws or prehensile tails. Within the various primate families, a diversity of ecological niches are occupied.

John and Prue Napier characterize quadrupedal primates as using fore- and hindlimbs together during walking and running. They have differentiated generalized quadrupeds and “semibrachiators”: In the former, arms and legs contribute about equally to locomotion; in the latter, the forelimbs are supportive, and the hind limbs are propulsive. Michael D. Rose points out that the term *quadrupedalism* can be used in two ways. It can be used to describe locomotor activity in which the animal stands and moves on all four limbs, locomotion is on horizontal or almost horizontal supports, and locomotion occurs above the support surface (in distinction to suspension). Rose also states that the term is used in a broader sense—to refer to a locomotor repertoire that has a major element of quadrupedal behavior in it.

Cercopithecoids as Models to Study Quadrupedalism

Because of focus on the evolution of extant hominoids from a Miocene stock, much of the detailed anatomical work and naturalistic study has focused on those species that have been characterized as brachiators or semibrachiators: apes and certain New World monkeys and Old World colobines.

The most taxonomically diverse and numerically successful nonhuman catarrhines are Old World monkeys. It is unfortunate that Adolph Schultz’s generalization, that all cercopithecoids are similar in their postcranial morphology, has had considerable influence. Cercopithecoids have been considered to be a monolithic block of pronograde quadrupeds, not showing the adaptations that distinguish certain species of New World monkeys and basically similar in their locomotor behavior and postcranial structure. Because of the fundamental assumption of similarity in the postcrania of cercopithecoids, with the exception of studies that contrast colobines with cercopithecines, there has been a tendency to emphasize or assume similarities of fossil cercopithecoids to their closest living relatives. An example of this is the reconstruction of *Theropithecus oswaldi* as a digitigrade baboon without specific study of the hand or wrist bones. In addition, data from derived from experimental research on

quadrupedal representatives of other orders (such as opossums and cats) have been uncritically applied to quadrupedal cercopithecoids.

These approaches mask the variation that exists within and between cercopithecoid species. One comparison that has been made is between colobines and cercopithecines, in part because of the leaf-eating habits of colobines, the reduction of the thumb in African species, and the discovery of fossil forms such as *Paracolobus*; with the exception of “semi-terrestrial” forms such as langurs and the unusual fossil *Cercopithecoides*, the assumption has been that colobines should show features that are adapted to a more arboreal set of niches than the cercopithecines. While the comparison is useful, the taxonomic emphasis conceals fundamental differences between monkeys within the colobines and cercopithecines: that is, between palmigrade versus digitigrade types and between the more arboreal versus more terrestrial forms.

Since 1980, I have been engaged in a project that focuses on the locomotion of African cercopithecoids, especially extant *Cercopithecus aethiops* and extinct *Theropithecus oswaldi*, to answer questions of proximate and ultimate causation of quadrupedal behavior and anatomy. Cercopithecoids are ideal subjects because they are more “generalized” in their quadrupedal behavior than are species with specializations such as prehensile tails.

Contrary to the recent statement by Alan Turner and Mauricio Anton, in *Evolving Eden: An Illustrated Guide to the Evolution of the African Large-Mammal Fauna*, that vervet monkeys are always palmigrade in their locomotion, my own observation of vervets in the field and captivity demonstrates that some individuals are digitigrade while others are palmigrade; the precise distribution of this behavioral difference in the field has not yet been determined. The dichotomy would be considered unusual intraspecifically, because most species appear to manifest one hand posture or the other, but not both. It is an especially important

Quadrupedal locomotion in vervet monkeys on Lake Naivasha, Kenya. Field observation demonstrated that individuals were consistently palmigrade in hand posture. They actively foraged on the ground (left) and in the trees. In the terrestrial context, foodplants such as *Amaranthus hybridus*, *Oxygonum sinuatum*, *Sida cuneifolia*, *Cynodon dactylon*, and *Opuntia* were routinely consumed. In the arboreal context, the fruit of *Ficus praetoriae* and *F. wakefieldii* were eaten. *Acacia xanthophloea* provided gum, leaf buds, young leaves, flowers, seeds, and thorn bases; most of these items were consumed in the terminal branch setting but gum and red mites were eaten from the trunk and boughs (middle). The terminal branch setting provided extensive lateral contact between crowns, producing virtually continuous arboreal pathways for the monkeys (right) in their core area. There was seasonal variation in the consumption of some foods (e.g., *Acacia* flowers), which affected the amount of time spent terrestrially versus arboreally, while other foods (e.g., *Opuntia* pears and *Acacia* gum) are consumed during all seasons. While the Naivasha vervets ate at least 40 different species of plants, they were able to consume various items from yellow fever trees throughout the year.

control because behavioralists and morphologists are concerned with the effects of phylogenetic constraints and fabrication factors. In any study employing interspecific or intergeneric comparisons, there is an element of doubt whether the observed differences reflect differences in ways of life (niche) or whether they are due to phylogenetic or fabrication factors. One way of increasing the likelihood of correlating differences in form with differences in function is to perform intraspecific comparisons of populations in different habitats. Examples of this approach include K. A. Monk's study of grasshoppers, B. D. Patterson's work on chipmunks, S. L. Lindsay's research on Douglas squirrels, and R. F. Johnston's classic investigation of European sparrows. In the research on vervets, the problem of phylogeny is controlled to a great degree because much of the work is done with representatives of different local groups of the same species.

The aim of the research has been to correlate variations in hand-posture behavior (digitigrady

versus palmigrady) and in underlying morphology, with variations in local troop habitat structure and substrate preference. The proposition that is being tested is that digitigrady is correlated with habitual terrestriality and open habitat, while palmigrady is correlated with habitual arboreality and more closed habitat. I am therefore seeking to determine (1) whether there is a predictable relationship between behavior, morphology, and ecology; (2) whether certain kinds of African environments impose constraints on the adaptations of monkeys; and (3) whether these are represented simultaneously in their ecology and morphology. Study of forelimb anatomy of fossil *Theropithecus oswaldi* provides a perspective as

to whether some characters may be size related in their expression.

My research has a number of components (1) field study of the locomotor behavior and habitat of a palmigrade group on Lake Naivasha, Kenya, for comparison to a later study of digitigrade vervets; (2) trapping of individuals from the group that was studied in the field for electromyographic and cineradiographic comparison of palmigrady with digitigrady; and (3) osteological comparison of the forelimbs of species of African cercopithecoids, which have been described in the literature as either habitually palmigrade or digitigrade, examination of the range of variability within *C. aethiops*, and relation of intraspecific to interspecific differences between palmigrade and digitigrade forms. The results of all of these approaches would be too extensive to enumerate here, but some results of the electromyographic and cineradiographic in vivo experiments on primate quadrupedalism are presented below.

Experimental Study of Digitigrady and Palmigrady During Quadrupedal Locomotion

Electromyography was accomplished on two vervet monkeys and an anubis baboon. One vervet was a palmigrade adult female from Lake Naivasha. The second was a subadult male, born at the Institute for Primate Research, National Museums of Kenya. The male was a product of a cross between a digitigrade male vervet and a palmigrade female. The baboon was a late infant-early juvenile, trapped in the wild but obtained from a commercial primate importer, and was consistently digitigrade in hand posture. The research was accomplished in the facility of the Department of Anatomical Sciences, State University of New York at Stony Brook, with the kind permission and cooperation of Jack T. Stern, William Jungers, and Susan Larson. The muscles that were investigated were *flexor carpi ulnaris*, *flexor carpi radialis*, *extensor carpi radialis (brevis)* in the vervet and *longus* in the baboon), *extensor carpi ulnaris*, *extensor digitorum communis*, *flexor digitorum superficialis* (mainly to the third and fourth rays), and *flexor digitorum profundus* (mainly to the third and fourth rays). Eight experiments produced useful results. Two main questions were addressed: (1) Are the patterns of muscular activity different during support in habitually palmigrade monkeys versus habitually digitigrade monkeys? and (2) are the patterns of muscle activity similar to those documented in knuckle-walking apes?

Two sequences of quadrupedal walking in a young male *Papio anubis*: digitigrade walking (with thumb intermittently contacting surface) on a horizontal branch (top) and fast digitigrade walking on the ground (bottom). *Flexor carpi radialis* is active during most of support and starts activity prior to touchdown. In the terrestrial sequence, activity of *extensor carpi radialis longus* coincided with *flexor carpi radialis*. There was a period of overlap between *extensor digitorum longus* prior to touchdown with the other two muscles but its activity ended at or just before touchdown. Adequate recordings were not obtained from *flexor digitorum superficialis* in this experiment.

Source: Copyright © and courtesy of Paul F. Whitehead.

In experiments in which the flexors and extensors of the wrist were simultaneously recorded, there was in-phase activity of *flexor carpi ulnaris*, *flexor carpi radialis*, and *extensor carpi ulnaris*. Activity would

Quadrupedal walking in the hybrid male vervet. *Extensor digitorum communis* was active only during swing phase and was out of phase with the activity of the two flexors; its activity stopped at touchdown as in the baboon. The activity of *extensor carpi radialis brevis* was low, sporadic, and difficult to interpret: It may be serving to adjust the position of the hand rather than as a prime mover. Activity of *flexor carpi radialis* and *flexor digitorum superficialis* were simultaneous during support.

Activity of muscles in the palmigrade female baboon. As in the hybrid male, *extensor digitorum communis* and *flexor digitorum superficialis* were active during different phases of the step cycle. *Extensor carpi radialis* appeared to show two discrete bursts of low activity: one during swing phase and a smaller one at touchdown. Adequate recordings of *flexor carpi radialis* were not obtained in this sequence.

commence immediately prior to touchdown and continue during the major weight-bearing portion of support phase (see Figure 2).

During trot in the male and female vervets, there were distinct bursts of activity in these muscles. At the start of activity, the hand is roughly parallel to the substrate and the fingers rectilinear to the palm. The major activity of *flexor carpi ulnaris* and *radialis* end when the proximal phalanges begin to be lifted from the substrate; at this point, the metacarpals have just passed the perpendicular in support. Activity of *extensor carpi ulnaris* may continue for a slightly longer period; its burst of activity appears to end when the tips of the distal phalanges are about to leave the substrate.

Activity of *flexor carpi ulnaris* in the baboon is initiated while the hand is outstretched during swing phase: The fingers are rectilinear to the long axis of the antebrachium. The hand and antebrachium are moving cranially as a unit, and the hand is about to begin descent toward the substrate. Muscular activity begins at this point during both fast digitigrade walking on the ground and moderate digitigrade walking on a branch. Activity of *flexor carpi radialis* is similar.

In the baboon, the activity pattern of *extensor carpi ulnaris* often appeared to consist of two bursts separated by a short interval. These bursts occurred just at the beginning of, and near the end of, support. Major activity of the second burst stops abruptly as the metacarpals assume a perpendicular orientation relative to the substrate, rectilinear to the antebrachium. Subsequent to this, the proximal phalanges are lifted from the substrate, and *flexor carpi ulnaris* stops its activity. Generally, there is no activity of either *extensor carpi ulnaris* or *flexor carpi ulnaris* as the hand is lifted off the substrate and begins cranial swing.

Extensor digitorum communis is out of phase with the wrist flexors in all three animals and is active throughout most of swing. It stops its activity at touchdown, when there is a burst of activity of *extensor carpi ulnaris*. Full extension of the fingers in humans is produced by a combination of *extensor digitorum* and the lumbricals; the latter resist the tendency to flex at the interphalangeal joints during extension at the metacarpophalangeal joints. Unfortunately, clear results for the long digital flexors were not obtained in the baboon. However, good recordings for both vervets clearly demonstrate that *flexor digitorum superficialis* and *flexor digitorum profundus* are in phase in their activity and are active at the same time as the wrist flexors. Both digital flexors are active during support until the basal phalanges begin to be lifted from the substrate. The muscle that is the most difficult to interpret is *extensor carpi radialis*. Several experiments examined this muscle in the baboon and vervets. Activity was often low and irregular. These experiments did not elucidate its function (Figures 4, 5, 6, and 7)

Russell Tuttle and John Basmajian conclude that *flexor carpi radialis* prevents extreme ulnar deviation of the wrist during knuckle-walking in apes. This muscle seems to have this function in the examined cercopithecoids: both *extensor carpi ulnaris* and *flexor carpi ulnaris* are active during support, and both would be effective ulnar deviators. It is also certainly flexing the wrist, although it is

Simultaneous activity of *flexor digitorum profundus* and *flexor digitorum superficialis* during support in a terrestrial trot in the female vervet. Adequate recordings of *extensor carpi radialis* were not obtained in the experiment. *Extensor digitorum* coincided with the two flexors during a portion of its activity.

Digitigrade walk on the ground in the young male baboon. *Flexor carpi radialis* began its activity during the end of swing phase as the manus began its descent toward the substrate, and continued throughout most of support, ending after the antebrachium was perpendicular to the orientation of the phalanges on the substrate and the proximal phalanges had begun to be lifted from the ground. *Extensor digitorum communis* was active only during swing phase, ending its activity at touchdown. It both extended the digits from a flexed position and maintained them in the extended state until touchdown. Adequate recordings were not obtained from the other two muscles during the experiment.

Touchdown of the hand in a palmigrade male vervet studied by cineradiography during quadrupedal walking on a treadmill. The pisiform (P) maintains a horizontal orientation throughout the sequence and is nonweight-bearing. The metacarpo-phalangeal joints (MP) are closer to the substrate prior to and at touchdown than are the proximal ends of the metacarpals. In this regard, palmigrade touchdown is more similar to digitigrade touchdown than it is to human pedal plantigrady.

not clear how effective it is in resisting dorsiflexion because the palmigrade female vervet manifests significant activity in this muscle. Unlike results in the knuckle-walking gorilla, activity of *flexor carpi ulnaris* did not decrease while *flexor carpi radialis* remained active. Instead, *flexor carpi ulnaris* showed consistent activity. The result, together with my cineradiographic data on the orientation of the pisiform in digitigrade and palmigrade monkeys, suggests that *flexor carpi ulnaris* acts as the in-force for a first-class lever, because the muscle tendon continues as the pisohamate and pisometacarpal ligaments. Tuttle and Basmajian report little activity in *extensor carpi ulnaris* during knuckle-walking. In contrast, this muscle is consistently active during support in cercopithecoids. Studies by Tuttle and Basmajian and also Randall Susman and Jack Stern report relatively little activity of *flexor digitorum superficialis* and *flexor digitorum profundus* during knuckle-walking. In contrast, activity was recorded during support in both vervets. In the monkeys, *extensor digitorum communis* is not active during support and does not help to maintain the integrity of the joints during digitigrady in the baboon.

Finally, while there are still some gaps in our knowledge, there is a noticeable similarity in the muscular activity patterns of digitigrade and palmigrade cercopithecoids. This finding is explained by cineradiographic evidence that demonstrates that the phalanges are actually inclined downward toward the substrate prior to touchdown in vervet palmigrady: This gives the hand movements greater similarity to digitigrade touchdown than had been expected. In addition, the proximal metacarpals are always higher than are the distal metacarpals during support: this is another similarity to digitigrady and a significant difference from plantigrady in bipedal humans. (See Figure 8.) The extent to which similarity in hand movement between digitigrady and palmigrady may support the hypothesis of a semiterrestrial origin of the cercopithecoids is dependent on the relative genetic conservatism of the neurological bases of hand movement.

PRIMATOLOGY

Primatology is the study of nonhuman primates (NHP) or, as sometimes identified, the alloprimates, meaning primates other than us. The order Primates includes the prosimians, Old and New World monkeys, apes, and humans. The study of humans is relegated to the social sciences (that is, anthropology, geography, psychology, and sociology) and, although humans are primates, the study of humans is not included as part of primatology. Primatology, in contrast, is generally viewed as part of the life sciences. Nonhuman primates have been studied by psychologists, zoologists, and biological anthropologists in both the laboratory and in their natural habitats. In general, biological anthropologists study NHP under semi-natural conditions or in their natural habitat.

Primates are eutherian (that is, placental) mammals having, for example, hair, mammary glands for nursing their offspring, a physiology for maintaining a constant body temperature, and different types of teeth identified as incisors, canines, premolars, and molars. The traits unique to primates include an increase in brain size and a lengthening of all stages of the life cycle, stereoscopic vision with the eyes encircled by bones, color vision, sensitive ridged pads with nails at the end of the digits instead of the typical mammalian claws, opposable digits, and hands and

feet in place of paws. Primates also have a generalized skeleton and variable locomotor patterns and feeding postures.

The prosimians belong to the suborder Prosimii that includes the lemurs, sifakas, indris, and aye-ayes of Madagascar, the galagos of Africa, the lorises of Africa and Asia, and the tarsier of Asia. Prosimians have more retained (that is, primitive mammal-like traits) than the other suborder of primates, the Anthropoidea. These retained traits of the prosimians include a rhinarium or wet-nose, some claws, eyes not completely enclosed in bone, smaller brain size, and less control of individual fingers than seen in the anthropoid primates. The anthropoid primates, the monkeys, apes, and humans, lack the wet-nose, and have eyes completely encased in bone, relatively large brains, and nails on all of their digits. Some primatologists, particularly those who study early primate evolution, prefer to divide the order Primates into two suborders designated as the Strepsirhini, the wet-nosed prosimians, and the dry-nosed Haplorhini, which includes the tarsier, New and Old World monkeys, apes, and humans.

Primatology began in the 1800s as mainly a study of primate anatomy and an attempt to understand where primates, including humans, fall within the classification system constructed by Linnaeus in the mid-1750s. The first attempts to send researchers into the field to observe NHP in their natural habitat was initiated in the early 1930s by psychologist Robert Yerkes who sent N. W. Nissen and H. C. Bingham to observe chimpanzee (*Pan troglodytes*) and gorillas (*Gorilla gorilla*), respectively. Another psychologist supported by Yerkes was Clarence R. Carpenter who studied howler monkeys (genus *Alouatta*) and spider monkeys (genus *Ateles*) on Barro Colorado Island in the Panama Canal and arranged for 500 Indian rhesus monkeys (*Macaca mulatta*) to be moved to Cayo Santiago, an island off the coast of Puerto Rico. Carpenter was also part of the 1937 Asian research project to study gibbons (genus *Hylobates*) initiated by Harold Coolidge, Jr. Sherwood L. Washburn, who would play a major role in the development of primatology following WWII, was also part of the Coolidge expedition.

Following the aftermath of World War II the study of alloprimates in their natural habitat began again. In the 1950s Japanese biologists started to study Japanese macaques (*Macaca fuscata*), but this work was not translated into English until 1957. The work of the

Source: © iStockphoto/Michael Roginkin.

Japanese primatologists is now accepted in the West, and Japanese primatologists publish in English language journals. In the late 1950s, Irvan DeVore, under Washburn, studied baboons (*Papio anubis*) in Kenya. Subsequently Washburn sent a series of University of California, Berkeley, graduate students, recruited from among those studying cultural anthropology, to observe a wide range of NHP. Washburn was mainly interested in what NHP might tell us about human evolution. Soon, however, anthropologists were studying NHP because the NHP are interesting for their own sake, and anthropologists have the best methods for studying the social lives of the alloprimates. Pioneering studies were conducted by Phyllis (Jay) Dolhinow (*Semnopithecus entellus* in India), Jane Lancaster (*Cercopithecus aethiops* in Africa), Donald Linburg (*Macaca mulatta* in India), and John Ellefson (*Hylobates lar*, Southeast Asia) among others. Beginning in the early 1960s, Louis Leakey, the great paleoanthropologist, sent researchers to conduct long-term studies of the great apes. Leakey sent Jane Goodall to study chimpanzees (*Pan troglodytes*), Dian Fossey to study gorillas (*Gorilla gorilla*), and Biruté Galdikas to study orangutans (*Pongo pygmaeus*). For the next 30 years, most studies of NHP in their natural habitat were carried out by students of Washburn or students of students of Washburn. Other early primatologists of note include Charles Southwick (*Macaca mulatta* in India), Stuart Altmann, (*Macaca mulatta*

on Cayo Santiago), George Schaller (*Gorilla gorilla* in Zaire), and in Africa Thelma Rowell (*Papio anubis*), Han Kummer (*Papio hamadryas*), and Robert Hall (*Erythrocebus patas*).

The turning point in the development of the systematic collection of data on NHP was the 1974 article by Jean Altmann concerning sampling methods. Prior to 1974, data were collected *ad libitum*, that is, behaviors were recorded that were most easily observed. This method of observation resulted in an unsystematic data set not amenable to statistical analysis. After

1974, *ad libitum* methods gave way to more systematic observations that could be more competently analyzed by statistical techniques.

The first steps in the study of a group of primates is to habituate them to the presence of the researcher, and for the researcher to learn to recognize individual group members. The process of habituation can take a short or long period of time depending on many factors including the skills and endurance of the primatologist, the nature of the habitat, the prior experience of the primate group with people, and so forth. Once habituation is proceeding, data collection can begin. Successful data collection involves a stated problem or hypothesis, systematic methods of observations and recording, the use of an ethogram (or a defined list of behaviors that relate to the problem or hypothesis being tested), the identification of individual members of the group under study, and careful analysis of the data.

Fifty years of the study of the alloprimates resulted in many surprising and controversial discoveries. For example:

- Mating patterns do not necessarily follow from social systems. For example, a female (such as the patas monkey, *Erythrocebus patas*) may live in a polygamous social group but mate promiscuously.
- A species can have multiple social systems. Howler monkeys (genus *Alouatta*) and gray langurs

(genus *Semnopithecus*), for example, may live in uni-male groups or multi-male/multi-female troops.

- Multiple social systems may be adaptive to the same habitat. White-faced capuchins (*Cebus capucinus*) that live in multi-male/multi-female troops are sympatric in Central America with spider monkeys (genus *Ateles*) that have a fission-fusion social system.

- Among Old World monkeys, the fruit and insect eaters (subfamily Cercopithcinae) have larger brains for body size than the leaf eaters (subfamily Colobinae).

- Tool use has been observed among chimpanzees (genus *Pan*), orangutan (genus *Pongo*), and capuchins (genus *Capucinus*).

- For anthropoids, individual troop members recognize the vocalizations of other individual troop members, and vocalizations can have environmental referents such as bird or terrestrial predators.

- Social skills are more important in attaining and maintaining rank than body size or fighting ability.

- For anthropoids, but not prosimians, sexual intercourse may occur outside the female's fertile period.

- For anthropoid primates, but not prosimians, both heterosexual and homosexual behavior has been observed.

PROSIMIANS

Often used as models for early primate anatomy and behavior, prosimians include a rich diversity of species exhibiting a complex range of social behavior, dietary specializations, and locomotor habits. Although more geographically widespread in the past, today these generally small primates are restricted to the Old World. Five of the eight major prosimian groups are known exclusively from Madagascar, while other species are found in Africa and Asia. While prosimians are only distantly related to humans, this group has allowed scientists to identify common anatomical and behavioral traits that link all primates.

Traditionally, the order Primates is divided into two major suborders, Prosimii and Anthropoidea. The latter group includes monkeys, apes, and humans, while prosimians are comprised of eight distinct families, including the cheirogaleids, lemurids, lepilemurids (megaladapids), daubentoniids, indriids, galagids, lorisisds, and tarsiids. However, this Linnaean taxonomic arrangement has proven controversial, as several recent studies have shown that Prosimii isn't a natural, monophyletic group comprised of a single common ancestor and all of its descendants. Instead, this suborder is a basal grade of primates, linked by primitive characteristics, that includes those species more primitive than Anthropoidea. Modern primatologists have thus advocated a system that divides Primates into two large, monophyletic clades: Haplorhini, which consists of Anthropoidea and tarsiids, and Strepsirhini, which includes all of the traditional prosimian families with the exception of tarsiids. Although based on phylogenetic analyses that have found tarsiids to be closer to anthropoids than to the other traditional prosimians, this nomenclature is still not universally accepted. Thus, this entry will consider all eight of the traditional prosimian families, as well as a handful of fossil groups whose relationships are poorly resolved.

Source: © iStockphoto/Derek Dammann.

Depending on which classification scheme one follows, there exist between 24 and 31 genera of living prosimians, which are further divided into 54 to 68 species. All prosimians share with other primates several basic characteristics, including grasping hands with opposable thumbs, the primitive mammalian claw modified into a flat nail, forward facing eyes that result in binocular vision, large brains, small litter size, and slow growth. The clade Strepsirhini is united by three distinct features: an unusual dental “comb,” a grooming claw on the second digit of the foot, and a laterally flaring talus (ankle bone). The clade Haplorhini, which includes anthropoids and tarsiers, is linked by several features of the soft anatomy, mostly relating to the nose and lips. Overall, the traditional Prosimii (including tarsiers) exhibits a relatively primitive anatomy compared to later primates, including a small brain. As a result, prosimians—especially cheirogaleids and lorisids—have often been used by primatologists as models for the primitive primate condition. However, despite their retention of primitive features, prosimians are a successful group that exhibits a wide range of behavior.

Cheirogaleids

One of five prosimian families found exclusively on Madagascar, cheirogaleids are small-bodied,

nocturnal, nest-building primates. Their reproductive system is unique among primates, with females possessing three pairs of nipples and often birthing twins. Five extant genera are included in this group, all of which have a mass of less than 500 grams. The mouse lemurs (*Microcebus*) are arboreal quadrupeds that move by running along small branches and leaping between terminal twigs. Mouse lemurs are faunivorous and occupy overlapping home ranges. It has been observed that the sex ratio of individual litters is influenced by the presence or absence of females other

than the mother. Coquerel’s mouse lemur (*Mirza*) constructs large, circular nests of leaves for daytime resting, but spends the night feeding and socializing with conspecifics. The dwarf lemurs (*Cheirogaleus*) hibernate for long periods during the dry season, while the fork-marked lemur (*Phaner*) is characterized by a suite of features related to its diet of gum, including large hands and feet with expanded digit pads, keeled fingernails, and procumbent incisors. Unlike other cheirogaleids, *Phaner* lives in permanent groups, many of which contain one male and one female.

Lemurids

Likely the most well known of the prosimians, the lemurids contain the signature Malagasy lemurs, most of which are medium-sized (1–4 kilograms) and live in groups. The ring-tailed lemur (*Lemur catta*), marked by a long, striped tail, is the most terrestrial of the living strepsirhines, spending approximately 65% of its traveling time on the ground. *Lemur* has also been observed to live in large social groups of approximately 20, containing roughly equal numbers of males and females, which are dominant. The closely related *Hapalemur* feeds almost exclusively on bamboo, with the three recognized species each specializing on a separate part of the plant. The

mongoose lemur (*Eulemer mongoz*) exhibits variability in its activity pattern, diet, and social organization, with most populations consisting of monogamous family units.

Lepilemurids (Megaladapids)

Often grouped with the lemurids, the genus *Lepilemur* (the sportive lemur) is regarded by certain researchers as distinctive enough to warrant its own family, which also includes the extinct genus *Megaladapis*. *Lepilemur* is characterized by its small size and lack of permanent upper incisors, and is signified by one of the lowest basal metabolic rates of any primate. Sportive lemurs are solitary and extremely territorial, and males have often been observed to fight over their small home ranges.

Indriids

Characterized by long hind limbs used for leaping, the three extant indriid genera share many cranial features, but differ in size and activity patterns. The woolly lemur (*Avahi*), the only nocturnal indriid, lives in monogamous family units and is known to huddle in groups while feeding. The familiar sifaka (*Propithecus*) is a large, diurnal primate known from three species. Although the sifaka is primarily a vertical leaper while in the trees, it can hop bipedally on the ground. The sifaka normally lives in groups of three to nine, which often include multiple breeding females. Males regularly change groups, which results in strong male-male competition during the breeding season. The third indriid genus, the indri (*Indri*), is marked by long hands and feet, slender arms, and the absence of a tail. This genus is extremely vocal, and congregates in small family groups that defend large territories.

Daubentoniids

The single genus included in the daubentoniid family, the aye-aye (*Daubentonia madagascariensis*), is perhaps the most bizarre living primate. This moderate sized (3 kilogram) animal is differentiated by a suite of extreme anatomical characteristics, including a set of ever-growing incisors and a long, slender third digit of the hand. Captive studies have indicated that the aye-aye uses its unique third digit to tap logs, which can reveal the presence of insect prey. If insects

are located, the aye-aye will then gnaw at the log with its incisors and use its finger as a probe. The aye-aye is also known to be a non-seasonal breeder.

Galagids and Lorisids

United by a host of cranial features, the galagids and lorisids constitute a limited radiation of mainland prosimians. The African galagids (bushbabies) are represented by four genera, including *Otolemur*, *Galago*, *Euoticus*, and *Galagoides*. Among the best-studied galagids is the South African lesser bushbaby (*Galago moholi*), which has been observed to form social hierarchies related to age and weight. The needle-clawed galago (*Euoticus elegantulus*) is a specialized gum feeder, and has evolved procumbent upper incisors and claw-like nails to assist in food procurement. The lorisids, found in Africa and Asia, are characterized by their slow locomotion. The potto (*Perodicticus*) is the most widespread of the African lorisids, and specializes in olfactory foraging. The slender loris (*Loris*), which inhabits Sri Lanka and southern India, is a small, slim primate, while the slow loris (*Nycticebus*) is larger and moves by slow, quadrupedal climbing.

Tarsiids

Although of debated phylogenetic position, the tarsiids constitute the eighth and final living prosimian family. This group includes one genus, *Tarsius*, which is known from five species, all of which inhabit Southeast Asia. Sharing many soft-tissue characters with anthropoids, tarsiids are small primates characterized by extremely large eyes, which are larger than the brain. The hands and feet of tarsiids are proportionally large, and the living species show several adaptations for leaping, including a fused tibia and fibula and a long ankle region.

Adapoids and Omomyoids

Two diverse groups of extinct primates are also often included in Prosimii. The Adapoidea, which date from the early Eocene (55 million years ago), and became extinct approximately 8 million years ago, are traditionally described as “lemur-like,” although this description has been chided for being too simplistic. Primatologists recognize at least 30 genera and 80 adapoid species, and commonly this group is

placed in the Strepsirhini. The Omomyoidea also date back to the Eocene, and include some 40 genera and 90 species. Often described as “tarsier-like,” omomyoids are now classified in the Haplorhini. Based on phylogenetic analyses, it has been deduced that adapoids and omomyoids likely evolved in the Paleocene and, thus, are among the oldest known primates.

Prosimian Evolution and Significance

The question of primate origins has proven controversial, but it is widely accepted that primates are closely related to Scandentia (tree shrews), Chiroptera (bats), Dermoptera (colugos), and a diverse extinct group called Plesiadapiformes. The early fossil record of primates is patchy, but genetic and paleontological evidence indicate that the Strepsirhini-Haplorhini split occurred in the Paleocene (65–57 million years ago), and the anthropoid radiation was well under way by the late Eocene (40 million years ago). While adapoids and omomyoids are well known from fossils, the fossil record of other prosimians is poor. *Tarsius eoceanus* and *Xanthorhysis tabrumi* from the middle Eocene of China indicate that tarsiids diverged from other haplorhines before this time, but most other prosimian groups are known from only a handful of fossil specimens. Despite these drawbacks, it has been suggested that, among the strepsirhines, lorises and galagids form a monophyletic group. Additionally, there is support for a grouping of lemurids, indriids, and lepilemurids. The phylogenetic relationships of cheirogaleids and daubentonids are still widely debated.

Historically, it was argued that a prosimian (most likely a tarsiid) directly gave rise to the anthropoid line. The modern advent of cladistic analyses has frowned on such a notion, and now sees tarsiids and anthropoids as sister groups constituting the monophyletic Haplorhini. Regardless of the validity of a direct evolutionary connection, anthropologists can learn much by studying prosimians. Although only distantly related to humans, this diverse and successful group of generally small, primitive primates sheds light on the early evolutionary history of the human lineage, and showcases characteristics that link all primates.

Protolanguage is a term from historical linguistics that refers to the hypothetical, reconstructed ancestor from which a set of known languages is descended. The proto-ancestor is reconstructed using the comparative method, by which existing and/or historically attested forms are compared, and ancestral forms are reconstructed, which can yield the attested forms via regular sound and other changes. For example, the Proto-Indo-European form *mater* yields, by regular sound changes, forms as apparently distinct as English *mother*, Spanish *madre*, Sanskrit *matar*, Greek *mitir*, and Pashto *mor*.

Sir William Jones (1746–1794), a British colonial administrator stationed in India, was the first person to recognize the relatedness among the far-flung members of the Indo-European family. Since then, linguists and anthropologists have worked on reconstructions of several language families, including Proto-Jaqi (South America), Proto-Bantu (Africa), Proto-Austronesian (Southeast Asia), and Proto-Algonquian (North America).

The reconstruction of protolanguages has potentially important implications for anthropological research on prehistoric peoples. For example, if a word (for example, *birch tree*) can be reconstructed, it is at least plausible that the speakers of the protolanguage used the word in a sense related to contemporary senses, and, in this case, that birch trees were present in their environment. The reconstructed terms may provide clues to the geographical origin, material, and nonmaterial culture of its users.

Archeologist Colin Renfrew has carried this research farther than most.

Another important, and more recently introduced, use of the term protolanguage is in the sense of a prior stage in the evolution of human language. Bickerton and others have suggested that early hominins, such as *Homo erectus*, may have been capable of a form of language that lacked various design features of modern human language. It may have had a reduced grammar, especially in the realm of structure dependency and other syntactic principles, that made the language somewhat like the “telegraphic speech” of children around the age of 2 years; in fact, Bickerton has called the children’s two-word stage, as well as pidgin languages and the “sign language” learned by some apes, “fossils” of protolanguage. Bickerton has suggested that the crucial property lacking in these examples is hierarchical syntax.

It is important not to mix these two uses of protolanguage, and also not to confuse the evolution of language as a human species property with the language change documented by historical linguists between a reconstructed proto-language and its descendants. For example, the language changes that occurred between Proto-Indo-European and its descendants (for example, Greek, Hindi, and Gaelic), were not examples of language evolution, because no new design features or elements of universal grammar were added.

PSYCHIATRY, TRANSCULTURAL

Psychiatry is the branch of medicine that is concerned with the study, prevention, and treatment of mental disorder (aka mental illness and psychopathology). *Transcultural psychiatry* is an increasingly important specialty of psychiatry that focuses on cultural aspects of mental disorder and psychiatric practice. It has also been referred to as *comparative psychiatry*, *cross-cultural psychiatry* and, perhaps most commonly now, *cultural psychiatry*. Anthropologists, too, have engaged in the study of mental disorder, sometimes referring to their research as *psychiatric anthropology* but more commonly as *ethnopsychiatry*.

History

Emil Kraepelin, the founder of modern psychiatry, is also regarded as the first psychiatrist to make cross-cultural comparisons, which he did while working in a mental hospital in 1903–1904 in Java, where he conceived the idea of a comparative psychiatry. In general, however, transcultural psychiatry began with the establishment of mental hospitals in European colonies in the late 19th and early 20th centuries, leading Europeans to encounter and write about symptoms and syndromes that were exotic to them. One of the most important steps in the development of the field was the 1955 creation of a center for transcultural psychiatric research at McGill University in Canada. The center, founded by Eric Wittkower and Jack Fried, began to publish a newsletter that subsequently became the *Transcultural Psychiatric Research Review*. Anthropologists were regular readers of and contributors to the *Review*, which was replaced by the journal *Transcultural Psychiatry* in 1997. Transcultural psychiatry was at the margins of psychiatry for many years and is not quite mainstream even today. The American Psychiatric Association officially recognized it as a specialized field in 1969. In 1971 a Transcultural Section of the World Psychiatric Association was created through the efforts of H. B. M. Murphy, and the Society for the Study of Psychiatry and Culture was founded in 1979. National associations and university centers for transcultural psychiatry have appeared in England, Germany, Italy, China, and Japan in recent decades, attesting to the growing importance of the specialty in this era of globalization.

In the 1920s, American anthropologists began to develop psychological approaches to the study of culture, drawing on psychoanalytic theory in particular, in the “culture and personality” movement that eventually gave rise to psychological anthropology in the 1970s. One of the main issues of the movement, first raised by Ruth Benedict in her 1934 article “Anthropology and the Abnormaland” in her popular book, *Patterns of Culture*, was the cultural relativity of normal and abnormal behavior. Between 1933 and 1946, Abram Kardiner, a psychoanalyst, collaborated with Ralph Linton, an anthropologist, in a famous and long-standing seminar in New York on applications of psychoanalysis to the study of culture. In the process, Kardiner and Linton developed a psycho-cultural model of society that included the concept of a basic personality structure and encouraged a generation of anthropologists to study topics such as personality structure, the self, identity, ego strength, socialization, and mental disorders in a wide variety of cultures. Another important development, conceived by the Haitian psychiatrist Louis Mars in 1946 and popularized fifteen years later by the anthropologist George Devereaux in *Mohave Ethnopsychiatry*, was the study of indigenous conceptions of mental disorder, their causes and treatment. Since 1977, the main forum for anthropological studies of mental disorder has been the journal *Culture, Medicine and Psychiatry*.

There is a long history of engagement and collaboration between psychiatrists and anthropologists in the cross-cultural study of mental disorders, but there are also significant differences between the two disciplines—perhaps even more today than in the past.

Anthropology and Psychiatry

Psychiatry is a branch of medicine, western in origin, and focusing on the biology of disease. The western mind/body dualism is reflected in the division between mental and physical illnesses. American psychiatry employs a *Diagnostic and Statistical Manual of Mental Disorders* that was developed to identify disorders in western society but is, however, assumed to be a universally applicable or *etic* system. In response to criticisms from anthropologists and transcultural psychiatrists, an attempt was made to address cultural variation in the latest version, *DSM-IV*.

Cultural anthropology or ethnology is the scientific and humanistic study of the ways in which

people construct a common framework of meaning, discourse, and institutions to guide their lives. Anthropologists seek to understand a society first of all from the perspective of its cultural knowledge, that is, from the *emic* perspective, and try to avoid imposing concepts that can distort cultural realities. Anthropologists offer a “thick description” of local knowledge that is essential to understanding a group of people, but the *emic* approach can make it difficult—some say impossible—to compare cultures and test theories. The methodology of anthropology is based largely on participant-observation and interviewing, whereas psychiatry relies on assessment instruments, experiments, epidemiological research, and statistical analysis.

There are obviously several fundamental points of contrast, if not conflict, between the psychiatric and the anthropological approaches—biological vs. cultural, *etic* vs. *emic*, universalist vs. relativist, quantitative vs. qualitative—and it remains to be seen if they can be bridged. Psychiatry is, however, becoming an increasingly diverse and international profession, with a growing number of nonwestern practitioners and centers. Some nonwestern practitioners are finding western psychiatry inapplicable, inappropriate, ineffective, or incomplete in their cultural settings and are seeking more culturally sensitive concepts and practices.

Topics and Questions

Transcultural psychiatry investigates a fascinating and important range of often controversial questions, issues, and subjects that can give us unique insights into being human, as well as meeting human needs. One of the most basic questions is how to distinguish normal from abnormal behavior—by a universal standard or according to the norms of a culture? Another issue is the classification of disorders; in particular, is the American *DSM* adequate for use in all cultures?

One of the first major subjects of research in this field was cross-cultural variations in the rate of mental disorders, which gave rise to numerous epidemiological studies. The rate of disorder among immigrant, minority, and refugee groups has also been examined extensively. Cultural influences on symptoms are another important topic. Depression, for example, is typically experienced as psychological or existential and associated with feelings of guilt and

suicidal ideation in western societies, whereas it is more commonly somatized as a physical condition in nonwestern cultures.

A major cross-cultural study on schizophrenia was conducted by the World Health Organization in the 1970s. The main conclusions were that core symptoms of the disease are identifiable cross-culturally, and that there is little cross-cultural variation in the incidence of the disorder. On the other hand, the study determined—perhaps surprisingly—that the outcome of schizophrenia is more favorable in less developed countries than in more developed countries.

Abnormal thoughts, feelings, and behaviors that correspond to mental disorder are probably recognized in most, if not all cultures, but there are many different ways of conceptualizing and explaining them. The largely anthropological study of ethnopsychiatry focuses on folk or indigenous nomenclature and classifications of disorders, recognized symptoms, beliefs about etiology or cause, and expectations about the course of a disorder. Indigenous explanations may include biological or physical factors such as hard work or fright and psychological explanations such as envy or excessive worrying, as well as moral, social and supernatural causes such as infractions of norms, conflicts in social relationships, soul-loss, demonic possession, witchcraft and sorcery. Ethnopsychiatric conceptions provide the framework for the subjective experience of an *illness*, which should be distinguished from the clinician's biomedical knowledge of *disease*.

Another important topic is how mental disorders are treated in nonwestern societies. Are shamans, priests, and traditional healers “folk psychiatrists,” as E. Fuller Torrey suggested in his 1986 *Witchdoctors and Psychiatrists*? How does traditional healing differ from psychiatry? What do they have in common? How do they compare in efficacy? What can psychiatry learn from traditional healing? In addition, is participation in some cultural practices, customs, and institutions—such as trance and possession, shamanism, and other altered states of consciousness—cathartic, protective, or therapeutic, as many have suggested?

Much of the research in transcultural psychiatry has been primarily theoretical, but more attention is now being paid to clinical applications. Does successful therapy require a shared worldview, as Jerome D. Frank argued in *Persuasion and Healing* in 1974? If so, then can western psychiatry be effective in nonwestern settings? How much cultural knowledge does one

need to know and use to properly diagnose and treat a patient?

Another prominent topic of interest in the field is the so-called Culture-Bound Syndromes: over 186 mental disorders that are believed to be unique to particular cultures. They include *susto* in Central America, *amok* in Indonesia, *ataque de nervios* among Hispanics in the U.S., *latah* in Malaya, *pibloktoq* or Arctic hysteria among the Inuit, *koro* in China, and *anorexia nervosa* in the U.S. Opinion is divided on whether they are truly unique or whether they are culturally elaborated forms of universal diseases. In any case, they demonstrate that culture can and does significantly shape the appearance of mental disorders, if it does not cause them.

Anthropologists are particularly interested in how communities respond to mental disorder. Does mental disorder carry a stigma in all cultures? How common is ostracism or abuse? Are some cultures more tolerant or supportive than others? How do individuals with mental disorders seek help? To what extent is illness behavior, including mental disorders, a social role that follows a cultural script that has been learned, once a person has been assigned a label? Does a disorder follow a particular course because of the disease process or because of cultural expectations?

Many topics of research in transcultural psychiatry require expertise in psychiatry, but there are at least three subjects where anthropological expertise is more important. Two of the subjects are ethnopsychiatry and traditional healing practices, as discussed above; the third is the ethnographic study of psychiatry itself as a subculture and as a social institution, which was pioneered in 1958 by William Caudill in *The Psychiatric Hospital as a Small Society*. Anthropologists have also conducted participant-observation studies of a suicide ward and a psychiatric out-patient clinic in the U.S. Roland Littlewood and Maurice Lipsedge explored racism in the practice of psychiatry in Britain in *Aliens and Alienists*, published in 1997, and in 2000, T. L. Luhrmann offered an ethnographic examination of American psychiatry based on participant-observation in *Of Two Minds*.

Transcultural psychiatry began as the study of mental disorders in “other” cultures—namely, nonwestern and often colonial societies—from the perspective of western psychiatry. The fact that the western psychiatrist and the western patient also have a culture was largely ignored, perhaps because it is harder to perceive your own culture than another.

However, western patients and doctors also think and act according to the schemas of their cultures; they learn to feel and express their thoughts and emotions in culturally constituted ways, and these ways of thinking and feeling are often institutionalized, even in science and medicine. Studying the cultural context of mental disorders in *all* societies can give us new perspectives on mental disorder as well as the culture and practice of psychiatry, possibly leading to a truly global psychiatry.

PSYCHOLOGY AND GENETICS

Psychology and socialization research examine the workings of the human mind and human behavior; genetics, as a branch of biology, examines the way in which traits and predispositions are transmitted from parents to their children as a result of genetic recombination.

The relationship between psychology, in contrast, and biology and genetics, has never been easy. But what makes it so difficult? It is not simply that the past still casts a long shadow on the relationship; there are other, conflicting explanations. Both psychology and genetics claim they can explain human

development and behavior; a basis common to both disciplines is their acceptance of the intergenerational transmission of knowledge and skills, attitudes and behavioral predispositions. Psychology and socialization research, however, regard such transmission primarily in terms of social learning theories, while research with a biological and social orientation addresses culture's biological and cultural transmission. Psychologists find it difficult to accept that higher cognitive functions (for example, free will, conscience, and religious attitudes) can be subject to genetic control. Geneticists accuse psychologists of simply describing human behavior while failing to explain it. From the psychologist perspective, genetic explanations are suspected of being deterministic. Must these positions remain irreconcilable for all time?

For approximately 20 years it has been possible to observe a gradual increase in willingness in psychologists to consider biological and genetic approaches when explaining human development and behavior. Key words, such as *sociobiology*, *neurobiological science*, *human behavioral genetics*, *evolutionary psychology*, *life history theory*, and *evolutionary socialization theory*, are increasingly encountered. In the United States, especially, this willingness is seen in the context of the revival of Darwinist theories in the social sciences. Several fundamental questions in biological and evolutionary behavioral sciences have a long history.

While the term genetics (coined by William Bateson in 1906) is of much more recent origin than psychology, the debate about whether nature or culture is the stronger force has a far-longer pedigree. The Latin poet Horace (65–8 B.C.) wrote “*Naturam expellas furca, tamen usque recurret*” (you may drive nature out with a pitchfork, yet she'll be constantly running back). Nature and nurture as a pair of concepts can be found in Shakespeare's *The Tempest* (first performed in 1611), which also deals with the opposition of nature and culture. As Prospero remarks of Caliban: “A devil, a born devil, on whose nature / Nurture can never stick; on whom my pains, / Humanely taken, all, all lost, quite lost.” Approximately 250 years later, a fellow Englishman, Francis Galton (1822–1911), introduced the nature and nurture concepts into scientific language in his work *English Men of Science. Their Nature and Nurture* (1874). Galton, a cousin to Charles Darwin, believed that mental qualities and success in the sciences, the arts, and public life were far more strongly determined by hereditary factors

than was generally assumed. He conducted studies of families and established the basis of twin and adoption research—its methodology and use of correlation statistics. Galton and his followers were the first behavioral geneticists (biometricians), and in relevant specialist literature today Galton is acknowledged as having been the father of human behavioral genetics long before the term even existed. This line of research is now referred to as *quantitative behavioral genetics*.

In *The Expressions of Emotions in Man and Animals* (1872) Darwin developed the theory that held that reflex actions and the ability to express emotions such as anger and embarrassment must have been learned in evolutionary prehistoric times because very young children display them. As Darwin humorously observed, sneezing and coughing were inherited reflex actions, but children had to learn to use a handkerchief when blowing their noses. Darwin's study is a forerunner of present-day *evolutionary psychology*.

Although Darwin and Galton were convinced that both physical and mental traits were transmitted from generation to generation, they knew little about the function of heredity. It was not until Gregor Mendel (1822–1884) and August Weismann (1834–1914) each published their findings that the science of heredity took its current direction. *Modern Synthesis*, a movement in the 1930s and 1940s led by biologists T. Dobzhansky, J. S. Huxley, E. Mayr, and G. G. Simpson, sought to combine Darwin's theory of evolution by natural selection with Mendel's theory of heredity (genes as heritable elements). In so doing, Lamarck's theory of the transmission of qualities acquired over a lifetime was finally disproved and Darwin's theory of natural selection was provided with a firm genetic basis.

The forerunners of present-day *molecular genetics* also date back to more than a century. In particular, the school founded by the American zoologist and Nobel prizewinner, Thomas Hunt Morgan (1866–1945), initiated a line of research that was likewise linked to the term behavioral genetics. Even if Hunt was an advocate of what is now referred to as classical genetics (Mendelism), several of his followers investigated chromosomes to discover the loci of the genes responsible for the development of certain gene expressions; thus, by association, Hunt was also responsible for the development of behavior in the widest sense of the term. Consequently, in order to distinguish it from classical genetics, this is referred to

as developmental genetics. For many years quantitative genetics and molecular genetics found little common ground, and they developed independently of one another; however, over the last 2 decades there has been an increasing amount of cooperation in which great hopes have been invested.

In 1883 Galton coined the term *eugenics*. In so doing, he combined a long-term research program to clarify genetic processes over successive generations and a program concerned with family policy, in a bid to replace weakening natural selection by artificial selection. In the years before World War I a worldwide eugenics movement was launched, and national eugenics societies were founded in many countries, including Germany, England, and the United States. The political implementation of the eugenicists' demands subsequently led to the introduction of legislation permitting compulsory sterilization on eugenic grounds. It should, however, be noted that such compulsory measures were never seriously contemplated in Great Britain, the birthplace of eugenics.

The scientific basis of old eugenics was behavioral genetics and population genetics. In contrast to their successors today, the proponents of old eugenics, moving in the direction of genetic determinism, tended to vastly overinterpret the findings of the science of heredity, and to dramatize the rate at which hereditary predispositions with undesirable phenotypic traits—such as feeble-mindedness—spread. Mendel's genetic laws were applied equally to physical traits and to mental strengths and weaknesses. The American anthropologist and eugenicist Charles Davenport (1866–1944) attempted to prove that nomadism was genetically determined in Mediterranean peoples, and, similarly, that thalassophilia—love of the sea—was genetically determined in American naval officers. In the 1920s, following the preparatory work undertaken by Galton and his follower Karl Pearson (1857–1936), twin research based on correlation statistics was developed, and to this day it remains the methodical core of quantitative behavioral genetics.

The abuse of biology and genetics perpetrated in the service of social Darwinism and eugenically motivated compulsory sterilization meant that after World War II environmental and learning theoreticians dominated psychology and socialization theory. Today a confused belief persists that the battle against discrimination and racialism can be justified by advancing the argument that mankind is genetically

equal. Ideologically loaded, biased research has constantly provided new sustenance for this confusion, as was the case in 1994 when the psychologist Richard J. Herrnstein and the political scientist Charles Murray attempted to prove that differences in intelligence existed between different human races. For fear of being accused of racialism, many psychologists and other social scientists chose to defend politically correct environmental attitudes even when the evidence pointed in the opposite direction. However, an increasing number of scientists began to realize that a politically correct rejection of academic evidence offers no protection against racialism. Racialists could not be discouraged from being racist simply by advancing the argument that mankind was genetically uniform, regardless of the argument's accuracy. The renowned behavioral geneticist, Robert Plomin, has stressed that the principle of equality enshrined in the U.S. Constitution referred not to genetic uniformity but to equality before the law. In all democratic societies everyone should be treated equally—despite genetic differences. Psychologists have increasingly sought to overcome the problem presented by the traditional nature/nurture argument. Critical of the fact that, for far too long, psychology had played the claims of nurture against those of nature, they demanded the establishment of a modern synthesis of biological and socio-scientific theories, a synthesis that considered cultural, social, and biological factors equally and provided a better explanation of human development and behavior than either biological or socio-scientific theories alone could offer. Three major research areas with genetic implications are significant for psychology today: quantitative behavioral genetics, molecular genetics, and evolutionary behavioral science.

Quantitative behavioral genetics. As was true of biological sciences in general, quantitative behavioral genetics remained for many years anathema to psychology, because of its involvement with eugenics. J. L. Fuller & W. R. Thompson's 1960 *Behavior Genetics* was the first publication to use the term in its title. It was followed in 1970 by the foundation of the *Behavioral Genetics Association* and the specialist journal *Behavior Genetics*; despite this, the discipline retained its outsider status in psychology. This changed in the course of the 1980s and, in particular, in the 1990s. At its centenary annual conference in 1992, the American Psychological Association recognized genetics as a

research area that would be of major significance in the future of psychology.

Quantitative behavior genetics regards itself as an interdisciplinary subject-area situated between life sciences and psychology. Behavioral geneticists use statistical methods to disentangle the contribution made by genes and environments to personality differences. Personality traits are behavioral traits inasmuch as they show up in test scores. Behavioral traits measurable by specific test procedures include IQ, shyness, and religious attitudes, or the traits listed in the *Five-Factor Model of Personality*, also known as "the big five" (extraversion-introversion, agreeableness, conscientiousness, neuroticism-anxiety, and intellectual openness). The genetic factor is controlled using a classical research model that examines monozygotic and dizygotic twins, sibling children, and adoptive children; the environmental factor is controlled by examining twins who have grown up either apart or together. The term *behavioral genetics* is misleading in the sense that it can imply that, as a line of research, it is concerned primarily with the effectiveness of genetic influences; this is a misconception. To establish the contribution of genetic factors involved in shaping personality traits, a calculation of the contribution of environmental factors is an essential precondition. Heritability is the assessment of relationship between genetic variance and variance of behavior. The statistical value for heritability lies between 0.00 (where the total variance is attributable to environmental factors) and 1.00 (where the total variance is attributable to genetic influences). The more behavioral genetics learns about genetic predispositions the more it will also learn about the environments in which these predispositions acquire their phenotypic form. The findings of behavioral genetics also imply, however, that the influence of environments—the family environment, for example—is smaller than assumed by psychology and socialization theory, neither of which is informed by behavioral genetics.

The relationship between genetic predisposition and the environment is dynamic. The concept *genotype × environment correlation* implies that human beings undergo three developmental stages before reaching adult age: passive, reactive, and active genotypes × environment correlations. The passive stage occurs when children passively inherit family environments from their parents, environments that correlate to the children's genetic predispositions.

Reactive genotype $\times$ environment correlations describe the elicitation of responses from other individuals, based on the individuals' own genetically based personalities. The active stage occurs when individuals choose, change, construct, or reconstruct environments that correlate to their genetic predispositions. The interaction of genome and environment depends on an individual's age, in the sense that the influence of genetic predisposition does not simply stabilize with increasing age but actually increases. The earlier in their lives individuals can choose and actively shape their environments, the stronger the effect of genetic predispositions will be.

Molecular genetics. In the last 2 decades quantitative behavioral genetics and molecular genetics have moved closer to one another. Currently, there are high hopes of an increase in the amount of cooperation. Behavioral genetics works solely on a statistical level with genetic predispositions for behavior while molecular genetics looks for genetic loci in the genetic material (DNA molecule); these are known as *quantitative trait loci* (QTLs) and are connected to behavioral traits. This development was preceded in the 1980s by the discovery made in molecular genetics of how to use *DNA markers for gene mapping*. Molecular geneticist Lee M. Silver has recently predicted that, as their knowledge continues to grow, molecular geneticists will one day be in a position to establish connections between genetic profiles and those mental traits that we normally refer to as one's innate talents.

Behavioral genetics hopes that the identification of QTLs will provide direct proof of the existence of genetic predispositions for behavior. But genes are not directly involved in the regulation of behavior; rather, genes regulate the production of proteins. Between the genetic basis and behavior are morphological, neurophysiological, metabolic, and other levels of control. Bidirectional connections exist between all of these with the result that genetic activity exerts an indirect influence on behavior, and, conversely, behavior exerts an indirect influence on gene activity. This means that of all interacting levels the behavior level is furthest away from the genetic basis. Thus, the protein products of the QTLs must be investigated in order to demonstrate how the product of a QTL influences a particular measurable aspect of behavior between the various levels.

But what does molecular genetics know about behavior? In this respect molecular genetics is dependent

on behavioral genetics for information about what precisely constitutes measurable behavior in order to know which QTLs and protein products it should be seeking. This may be relatively simple, as in the case of Huntington's disease (in 1993 the causal gene was discovered on chromosome 4), for example, but it is a different matter with complex personality traits such as shyness or sociability. Thus, it is not surprising that several skeptics can be found among biologists, such as Richard C. Lewontin, for example.

Evolutionary behavioral science. Present-day evolutionary behavioral sciences are rooted in European *human ethology* and in American *sociobiology*. Edward Osborn Wilson's 1975 study *Sociobiology: The New Synthesis*, a highly contentious book at the time it was first published, was significant first and foremost in that it introduced the term sociobiology; however, it contributed little to the understanding of the evolutionary biology of human beings. The final chapter in this bulky work is devoted to human beings, but is only 29 pages in length.

Evolutionary approaches have meanwhile become so numerous that one can talk in terms of the evolution of evolutionary perspectives. They all assume that species-typical behavior has been genetically acquired in an *environment of evolutionary adaptedness* (EEA). Seen from this perspective, personality traits have distal and ultimate causes, but they are triggered, influenced, and modified by proximal internal and external stimuli. An ever-increasing number of publications in this field may be classified according to three different approaches in evolutionary behavioral sciences: *evolutionary psychology*, *evolutionary ecology*, and *evolutionary cultural anthropology*. Evolutionary theory is seen as a broad integrating framework for embracing almost all subdisciplines of psychology, including behavioral genetics.

It would be almost impossible to conceive of this revolution in evolutionary behavioral sciences without William D. Hamilton's 1964 doctoral thesis, *The Genetical Evolution of Social Behavior*. In this work Hamilton demonstrates that the classical concept of fitness, which ascribes genetic reproductive success to an individual, fails to provide an adequate explanation of evolution by selection. In brief, Hamilton's *inclusive fitness theory* holds that an individual will also promote the reproduction of his genes by behaving altruistically toward his genetic relatives because these relatives carry copies of his own genes in varying

amounts, according to the degree of relationship. Inclusive fitness has two components: the reproductive success of an individual (*classic fitness*), and the reproductive success of his genetic relatives (*kin selection*). Before Hamilton's work was published, altruistic behavior was considered to be an alien element in evolution theory, but he succeeded in making it functionally explicable within the framework of his inclusive fitness theory. Three pioneering works by Robert Trivers, published in the early 1970s, were also of immense significance: *The Evolution of Reciprocal Altruism* (1971), *Parental Investment and Sexual Selection* (1972), *Parent-Offspring Conflict* (1974). These works, and the many studies based on them, provide the basis for the late 1990s new model of psychology: *Evolutionary Psychology*.

Below the theoretical level of inclusive fitness theory, one research concept has emerged that, in the opinion of certain researchers, is the most dynamic among all the evolutionary approaches to human behavior: *Life History Theory*. This theory examines the strategies of optimal generative reproduction in the life cycle. Clearly, generative reproduction is of direct relevance only to each generation of parents, but it is also active in generations that have not yet begun to reproduce (childhood/youth), or that no longer reproduce (old age); thus, the entire life cycle is regarded in terms of *reproductive strategy*. This means that each individual must perform a series of *developmental and judgment tasks* specific to his or her relevant age and dependent on his/her environment. In so doing, the individual must choose between different functional equivalences of inclusive fitness—such as age, survival resources, growth, development, information, and generative reproduction—because these equivalences are mostly limited and must be employed differently in different environments: survival versus growth, development versus reproduction, growth versus reproduction. In evolutionary life history theory, the judgment problem that dominates all others is the problem connected with current and future reproduction. With regard to parents, this implies *mating, parenting, and parental investment*. Mating denotes the act of reproduction (i.e., progeny in the quantitative sense); parenting and parental investment denote future reproduction (i.e., progeny in the qualitative sense). The surprising assumption is that within the specific conditions of scarce resources and insecurity about the future it can be functional for inclusive fitness for an individual to generate a

larger number of offspring whereas conditions of plentiful resources and security about the future can lead to the generation of fewer offspring. In the first case, the emphasis of reproduction strategy falls on mating in an attempt to increase the likelihood that *some* offspring will survive and to reduce the danger of elimination from the gene pool; in the second case, both parenting and parental investment will increase the reproductive value of a smaller number of offspring (health, longer period of development, mating prospects) and, thus, the inclusive fitness of future generations will be enhanced.

A traditional problem of personality psychology is currently being addressed anew, from the perspective of evolution: What makes one human being like other human beings, and what makes him or her unique? Psychology experiences difficulties in establishing a clear theoretical position between universal statements about man in general and statements about individuals. Until now the answer to the problem has been that human nature is equipped with uniform psychological mechanisms, which, as a result of distinct individual experiences, lead to individual differences. However, this answer fails to consider the problem of individuals' genetic differences, differences that challenge the concept of a universal human nature. The tension between individual uniqueness and the concept of a universal human nature has a parallel in evolutionary biology. Here theories about species-typical behavioral adaptations conflict with the discovery of major genetic variability (i.e., every individual has a unique combination of alleles [different forms of genes]). Evolutionary psychologists attempt to solve the problem by applying evolutionary logic to both the psychological universals that constitute human nature and the genetic differences that contribute to individual variation. Evolutionary psychologists John Tooby and Leda Cosmides believe that every personality phenomenon can be analyzed either as an adaptation, an incident byproduct of an adaptation, or the product of noise in the system, or as some combination of these three.

The problem of psychological universals versus genetic difference concerns the relationship between evolutionary psychology and quantitative behavioral genetics because behavioral geneticists are interested primarily in individual differences and less in human universality. It remains to be seen whether these two lines of research can complement and enrich one another for, despite the obvious thematic proximity

of the two, they have long since been regarded as independent disciplines, each concerned with different problems and methods. While it has long been claimed that each can benefit from the other and that in matters of central concern to both they are interdependent, only in the last few years has a rapprochement of the two been evident. In the view of the American psychologist Sandra Scarr, psychology will be truly evolutionary when the discipline includes behavioral genetics.

Behavioral genetics and evolutionary behavioral sciences share the belief that behavior and its development cannot be explained solely by reference to conditions here and now. Behavior geneticist Thomas Bouchard (Minnesota Twin Project) remarked that genes sing a prehistoric song. But what song do genes sing? The general direction of cross-fertilization between these two fields is this: evolutionary theories offer a broader framework within which the results of behavioral genetics may be interpreted while development genetics provides first and foremost the methods required to test hypotheses produced in the context of evolutionary theory.

The first revolution in life sciences, Darwinism, led ultimately to eugenics, a program for the genetic advancement of mankind. Many leading biologists in the 20th century, including Thomas Hunt Morgan and Ernst Mayr rejected eugenics whereas other leading biologists, like Hermann Joseph Muller and Joshua Lederberg, welcomed it. The early promise of the program pursued by old eugenics ended in contempt for human rights and in countless acts of compulsory sterilization.

In the course of the revolution in gene technology and medical fertility treatment, new eugenics has been a topic for debate since the 1980s. Initially, critics of gene technology and reproduction medicine primarily spoke in terms of new eugenics. Conspiracy theories abounded. Businesses, insurance companies, and those responsible for health care policy are undeniably interested in genetic services. But it is unreasonable to place all science under suspicion, as if the driving force behind scientific interest was the intention to apply it in the service of eugenics. There is another alarming and perplexing development: unintentionally, even unwittingly, various branches of research in life sciences and reproduction medicine are now providing the scientific and technical potential to "rectify" the biological constitution of human beings.

In view of the steady growth of technical possibilities and of the resulting options for genetic screening programs (backdoor-eugenics) the debate conducted in the 1990s became more sophisticated, raising the question of the ethical position of so-called *liberal eugenics*. Liberal eugenicists maintain it is no longer enough to simply issue warnings about the dangers of playing God. They recognize the need for ethical regulation in order to avoid having to undertake a future battle about the equitable distribution of genes. Buchanan and others have written a detailed work entitled *From Chance to Choice* with the significant subtitle *Genetics and Justice* in which they ask several highly pertinent questions: Do we have the ethical resources to use our genetic powers wisely and humanly? Or are we like hapless space travelers embarking on an interstellar voyage equipped only with a pocket compass?

A central argument proposed by liberal eugenicists is that they derive the ethical basis for the genetic advancements of human nature from the individual's right to *reproductive freedom*. A further central argument classifies genetic investment in children as being on the same ethical plane as educational investment. If one believes it to be self-evident that wealthy parents in democratic societies can buy environmental advantages for their children, how can one justify preventing parents from buying genetic advantages, given that both serve the same aim (i.e., to improve the child's chances of a good life)?

Amazingly, in all the discussions of new and liberal eugenics the questions on which everything else depends is rarely articulated: What exactly is improvement of human nature? What should improved human beings look like, and how should they behave? Perhaps the simplest answer is that it is still too early to discuss the questions in detail. But when the time arrives, psychology will certainly be called upon to make its contribution even if, at this stage, it does not or will not recognize the fact. Psychology, given its access to the theory of evolution, biology, and genetics, is already playing the role of a participant who is not taking part. If scientific advance is not simply looking toward conducting genetic surgery (as in the case of Huntington's disease and other genetically caused diseases), but is really moving toward "improving" human behavior—engineering the human germ line—it will prove difficult for psychology, as an expert in behavior, to remain aloof.

Psychology and genetics have developed separately from one another for decades. During almost all of that period of time, quantitative behavioral genetics, which could have provided an integrating link, has had a divisive effect; the last 20 years can, however, be seen as a period in which perspectives have grown closer. Quantitative behavioral genetics, molecular genetics, and evolutionary theory, are all steering a course that will ultimately lead to convergence and cooperation. A new conceptual framework, evolutionary psychology, has been established. It would be wrong to assume that this is merely a passing fashion. There will, of course, be periods of stagnation, and, while the environmentalists' ramparts may have been weakened, they have not yet been stormed. In the short term, those who would like to see the various research areas in psychology united beneath the umbrella of the theory of evolution may be disappointed. But, as is all too evident, the ideological zeal that once established the traditional divisions—between nature and nurture, mind and body, natural sciences and the humanities—is no longer the force it once was. Beyond these divisions are very promising discoveries to be made. Many regard human identity as being lost in the process. But who would dare to argue that this identity is better preserved by maintaining these divisions? Identity does not exist once and for all time; rather, we must constantly strive to acquire a new understanding of it, time and again. The history of mankind is the history of striving to acquire an understanding of human identity repeatedly. It is vital that all men and women on Earth should share in this identity, and that genetics should not be misused in order to create new inequalities.

FORENSIC PSYCHOLOGISTS

One of the most grim areas that comes to the attention of forensic psychologists is juvenile suicide, those tragic events involving people under the age of 18. A March 2004 report in the *Youth Violence Research Bulletin*, a joint project of the Centers for Disease Control and Prevention and the Office of Juvenile Justice and Delinquency Prevention, reveals the startling dimensions of this national juvenile health epidemic. "Between 1981 and 1998, 20,775 juveniles ages 7–17 committed suicide in the United States—nearly as many as were killed by homicide or were cancer victims. Males were the victims in 78 percent of these juvenile suicides. Over the same period, the suicide rate for American Indian juveniles was far higher than for any other race."

The statistical analysis of such a tragic loss of life is conducted by forensic psychologists to determine the cause of the loss of life. According to the report, "The number of youth ages 13–14 who committed suicide in the United States equaled the number who were murdered.

"Of the juveniles who committed suicide, 66 percent of the males and 62 percent of the females

were 17 years old. Sixty-two percent of juvenile suicides were committed with a firearm, 24 percent resulted from suffocation (primarily hanging), and 10 percent were caused by poisoning.

"While more than half of both boys (65 percent) and girls (51 percent) committed suicide with a firearm, girls were far more likely than boys to use poison (25 percent versus 6 percent, respectively)."

An alarming new public health crisis has directly impacted forensic psychology in the field of juvenile suicide. Besides many other factors, there is a suspected involvement of antidepressant medications as a cause—or contributing factor—in American youth taking their own lives. According to the Federal Food and Drug Administration, the organization now "asks manufacturers of all antidepressant drugs to include in their labeling a boxed warning and expanded warning statements that alert health care providers to an increased risk of suicidality (suicidal thinking and behavior) in children and adolescents being treated with these agents, and additional information about the results of pediatric studies."

— John F. Murphy Jr.

PU'UHONUA O HONAUNAU

Pu'uhonua o Honaunau National Historical Park is a culturally and historically significant site located on the West Coast of the Island of Hawai'i. The 182-acre preserve contains a *pu'uhonua* (place of refuge) that, until the early 19th century, served as a safe haven for defeated warriors, noncombatants, and individuals accused of breaking a *kapu* (taboo). A strict set of taboos often carried penalty of death, but offenders who reached the refuge were protected and absolved after a series of ritual procedures administered by the *kahuna pule* (priest). The *kapu* system was a set of regulations and prohibitions governing human behavior, the most ancient and fundamental *kapu* being the separation of sexes for eating. Other *kapu* were designed to protect the land, conserve resources, and pertained to farming, fishing, water usage, and waste disposal. Several such sanctuaries were located on each of the Hawaiian Islands and the concept of

pu'uhonua was more fully developed in Hawai'i than in any other Polynesian island group. The site at Honaunau was the most continuously active refuge and dates approximately from 1550 A.D. The traditional practices of the *kapu* system were abolished by Kamehameha II in 1819 and many temples were destroyed. However, because the bones of the Kamehameha dynasty were kept there, the site continued to be revered.

The park is situated on a lava slice that stretches along the coastline of three bays: Honaunau, Alahaka, and Ki'īlae. Flanking the park inland is the Keanae'e *pali* (cliff), which parallels the shore. The 100-foot high escarpment is 1,000 feet long and the numerous cave openings and lava tubes in the cliff face served as residences and burial chambers. The site is located four miles south of Kealakekua Bay where Captain Cook's ships, the *Resolution* and the *Discovery*, anchored in 1778.

The refuge is partially enclosed by a massive, well-preserved wall containing no mortar. The 10-foot high, seven-foot thick wall extends southwesterly for more than 600 feet before turning west and extending another 400 feet toward the sea. Within the enclosure are three *heiau* (temple) platforms. The most recent structure, *Hale o Keawe*, dating from approximately 1650 A.D., has been restored with a thatched *hale* (house), carved *ki'i* (images), and a wooden *lele* (altar) for offerings. This structure served as a mausoleum, housing the bones of at least 23 *ali'i* (royal chiefs), and it was believed that the *mana* (spiritual power) of the royal bones gave special protection to the *pu'uhonua*. However, in 1829, Queen Ka'ahumanu ordered the ancestral bones removed and the temple was dismantled. The area outside the enclosure includes the remains of royal residences, a fishpond, and canoe landing.

After lying in ruins for nearly a century, the *pu'uhonua* was designated a county park in 1920. In 1961, 180 acres were donated to the U.S. government by Bishop Estate (administrators of the estate of Princess Bernice Pauahi Bishop who died in 1884). Pu'uhonua o Honaunau became a National Historical Park in 1978 and is managed and interpreted by the U.S. National Park Service, which conducts cultural events, provides self-guided tours, and maintains a visitor center. More than 600,000 people tour the park annually and it is popularly referred to as City of Refuge.

PYRAMIDS

Pyramids can be found in many parts of the world in a wide variety of contexts and functions (for example, tombs, temples), from remains in Egypt and Central America to modern reconstructions. When we think of pyramids, however, no better examples exist than those from ancient Egypt, especially the pyramids at Giza. The term pyramid is derived from the Greek *pyramis*, meaning “wheat cake.” Although the ancient Egyptians knew pyramids as *mer*, they also referred to a pyramid capstone or the tip of an obelisk as *ben-ben*, which alternatively refers to a conical loaf of bread. The main age of the royal pyramid building occurred mainly from Dynasties 3–13, and as late as the early 18th dynasty (circa 2686–1550 B.C.), after which Egyptian royal tombs became mainly subterranean, rock-cut galleries, while many 18th- to 30th dynasty (circa 1550–332 B.C.) elite private tombs adopted pyramidal chapels above subterranean burial chambers. An estimated 100 Old Kingdom to Middle Kingdom pyramids concentrate in an area focusing near present-day Cairo, while northern Sudan contains Egyptian-derived pyramids at Meroe and Napata, built by the Dynasty 25 Kushite and later Meroitic kings and royal families to the south of Egypt.

The classic Old Kingdom pyramids represent the personification of the deceased kings (and late Old Kingdom queens), along with their creation, rebirth, and connections with the daily rising and setting of the sun. The four sloping sides of the pyramid reflect the concept of the rising solar deity and the ascension of the king to the heavens using the sun's rays as a

ladder or stairway. The pyramid existed as the eternal house of Pharaoh for his daily journey to and from the gods in the cosmos; it reflected aspects of creation by resembling the primeval mound rising from the waters of creation; the alignment of the entry passage with the circumpolar “imperishable” stars assisted the king's ascent to one of the potential destinations for his spirit in the afterlife.

Though Ancient Egyptian pyramids differ widely in their size, form, and construction techniques, they share many similarities. Pyramids contain subterranean tombs (sometimes associated with galleries), superstructures containing a mortuary temple, satellite pyramid for the king's spirit double (*ka*), an enclosure wall, a causeway, and a valley temple, where offerings could be made. The associated temples bore royal cult statues, scenes of offerings, storage magazines, and facilities for the royal funerary cult.

Archaeologists of the Pyramids

The first true archaeologist of the pyramids was the pharaoh Thutmose IV (circa 1401–1391 B.C.), who restored the Sphinx 1,100 years after the reign of Chephren. In the Roman period, the pyramids were a popular tourist attraction though many suffered extensive damage due to stone quarrying. Even in the 12th century A.D., the casing of the pyramids at Giza was still intact. The first modern visitor to record the pyramids was John Greaves (1602–1652), an Oxford astronomy professor. In the early 1800s, the Napoleonic survey scientifically described the pyramids. R. Howard Vyse investigated five stress-relieving chambers in the great pyramid in 1831.

Other well-known archaeologists whose work at the pyramid complexes greatly influenced modern investigations include G. Belzoni (1816), K. Lepsius (1840s), A. Marriette (1850s), W. M. F. Petrie (1887–1888), and G. Reisner (1920s). Recent and current investigations include work by M. Lehner (workman's village at Giza), Z. Hawass (pyramids of Giza), D. Arnold (El-Lisht), and M. Verner (Abu Sir).

Development of Pyramid Complex

The origins of the pyramids can be traced to pit graves of the predynastic period and mud brick tombs Dynasty 1 (circa 3050–2890 B.C.). Its origins lie in the concept of the primeval mound, one of the creation myths of ancient Egypt, in which the world

began by rising out of floodwaters. Slightly raised mounds (tumuli) covering early graves gave way to mud brick structures (mastabas) that grew in size and complexity over time. For the Dynasties 1–2 royal tombs at Abydos (in southern Egypt), the appearance of twin stelae and separate funerary enclosures anticipate the subsequent, unified pyramid complexes with linked pyramidal tombs and temples.

Following in the traditions of Khasekhemwy's late Dynasty 2 burial mound and separate funerary enclosure at Abydos (Shunet el-Zabib), King Djoser (circa 2630–2611 B.C.) commissioned his architect, Imhotep, to build a funerary complex at Saqqara (near Cairo). Djoser's burial superstructure began as a simple square mound of stone blocks, but evolved rapidly into a four-stepped and ultimately a six-stepped limestone pyramid. It was inside a large enclosure wall, measuring 278 meters x 595 meters and 62.5 meters tall, and contained a red granite-lined underground burial chamber. A series of adjacent underground galleries contain 11 burial shafts and blue-tiled chambers, representing a subterranean palace. The step-pyramid enclosure wall symbolized the walled capital at nearby Memphis and the land of Egypt, containing multiple components oriented north-south, such as twin northern and southern tomb chambers, twin palaces or chapels, twin courtyards, and a series of two types of cult shrines representing deities of southern and northern Egypt, associated with the royal jubilee festivals (the heb-sed festival of rejuvenation and kingship).

The Main Pyramid-Building Period

In the Dynasties 4–6 (circa 2575–2150 B.C.), Egypt's pharaohs built pyramids in a 42-kilometer span extending from Giza southward to Abusir, Saqqara, and Dashur. Dynasty 4 saw the advancement of the stepped form to sloped sides while Dynasties 5–6 had smaller pyramids, but larger and more elaborately decorated temples. Egyptian pyramid complexes had various features in common: a pyramid with a burial chamber, a satellite pyramid for the king's spirit-double (*ka*), a mortuary temple, an enclosure wall around

Source: © iStockphoto/Ekkehard Domning.

these components, and a causeway leading to a temple (a focus for embalming and the royal mortuary cult) and harbor in the Nile Valley. Although the mortuary temple's orientation changes from north-south to east-west from Dynasty 3 to Dynasties 4–6, the Old Kingdom's pyramid entrance remains aligned to the north to the circumpolar stars. At the advent of Dynasty 4, King Sneferu (circa 2575–2551 B.C.) built a transitional pyramid at Medium, which was first stepped, but soon became a true pyramid with flat sides. At Dashur, he also built the Bent and Red Pyramids, the former of which has a curious shape due to its angle being changed midway through construction. The Dynasty 4 necropolis at Giza contains the single surviving ancient Seven Wonders of the World; it represented a new royal cemetery and symbolized the consolidation of state power. The Great Pyramid, built by Khufu (circa 2551–2528 B.C.), rises to 146.50 meters, with sides measuring 230.35 meters each. Its core contains massive stone masonry and chambers filled with sand for stability in earthquakes. The interior contains a series of three, superimposed

chambers, beginning with an incomplete chamber (30 meters below ground), connected to a northern entrance emerging in the lower face of Khufu's pyramid. Khufu's sarcophagus remains inside the uppermost "king's chamber," which is accessed via the "great ascending gallery" lined with red granite. The "king's chamber" and the "queen's chamber" yield a pair of incomplete "ventilation" shafts that may have allowed the nightly departure and return of the pharaoh's soul. The southern side of the pyramid yielded pits for five funerary boats, of which two remain intact (one boat has been reassembled beside the Great Pyramid).

Khafre's (circa 2520–2494 B.C.) pyramid looks bigger than a great pyramid, being built on a more elevated area, but is actually 10 meters shorter. His complex includes a valley and mortuary temple, beside the Sphinx, which represents either Khafre or Khufu, who guarded the entrance to the underworld and was worshipped as Horemakhet, or Horus with the horizon. Khafre's beautifully constructed valley temple contains limestone, red granite, and alabaster. Menkaure's (circa 2490–2472 B.C.) pyramid, the smallest of the three Giza pyramids, has a complicated substructure, a red-granite-cased superstructure and a causeway flanked by three small pyramids for queens. Dynasty 5 saw changes in the mortuary temple, containing more relief decoration. Pyramids became smaller, the substructure was standardized, and the pharaohs built sun temples linking the solar cult with the royal mortuary cult. King Userkaf (circa 2465–2458 B.C.) built the first solar temple at Abusir. Sahure's (circa 2458–2446 B.C.) pyramid complex at Abusir has historically significant relief decoration, displaying international trade with Syria-Palestine, while his pyramid causeway depicts scenes showing aspects of the transportation and building of his complex, and ceremonial festivals linked to its completion. The pyramid of King Unas (circa 2356–2323 B.C.) is especially significant, bearing the first written texts ("Pyramid Texts") in his burial chamber and associated interior chambers and passages.

Later Pyramid Complexes

The Old Kingdom pyramids terminate with King Ibi's tomb in Dynasty 8 (circa 2150–2134 B.C.). The succeeding First Intermediate Period (circa 2134–2040 B.C.) contained different types of tombs for provincial

rulers, some of who may have used small pyramidal superstructures (for example, Kings Intef I–III in early Dynasty 11). The advent of the Middle Kingdom (mid-Dynasty 11 through Dynasty 12, circa 2040–1991 B.C.) saw the construction of Montohotep I's terraced tomb chapel and rock-cut tomb at Deir el-Bahri. The terraced mortuary temple may have had a small pyramid representing a primeval mound. Dynasty 12 witnessed the revival of large pyramid construction, albeit much smaller in scale than the Giza pyramids and built with mud brick cores and stone casings. These pyramids were located farther south, in Dashur, and Illahun and Hawara in the Fayoum. Kings Amenemhet I and Senwosret I tried to revive the pyramid-building traditions of the Memphite region to the north, but after their reigns, royal pyramid construction was limited. Dynasty 12–13 pyramid complexes are variously excavated, while the tombs of Dynasties 14–16 remain mostly unlocated. In the succeeding Second Intermediate Period, the pyramids of Dra Abu el-Naga in Thebes (modern Luxor) contain rows of small pyramids associated with the royal tombs of the Dynasty 17 (ending in circa 1532 B.C.). The neighboring mountain peak of el-Qurn at Thebes represented a natural pyramid for the royal tombs of Dynasties 18–20 (circa 1550–1070 B.C.), located mostly in the Valley of the Kings. The last royal pyramids were built in northern Sudan (ancient Nubia, circa 720 B.C.–350 A.D.) for the Napatan and Meroitic rulers. Of note, several Roman emperors adopted small pyramid-shaped tombs in Italy, adopting Egyptian designs.

Pyramids and Ancient Egyptian Religion

Pyramids had many connections with ancient Egyptian religion. The living pharaoh was the earthly form of the god Horus, and when he died he became associated with the god Osiris. The pyramids existed as a temple to the Horus-Osiris union and the sun god, allowing the ba (representing the life force), ka (representing individual qualities), and the body of pharaoh to unite, unifying life with death, and light with darkness. The mummification of the king probably occurred within the valley temple or in lighter structures in the pyramid complex. The Pyramid Texts, first found in the pyramid of Unas, are the oldest religious literature of ancient Egypt, and have allowed the pyramid complex to be interpreted more accurately.

How Were the Pyramids Built?

Although there is no specific, standard method for constructing pyramids, archaeological investigations have revealed different building methods for various pyramids. Although remnants of roadways with logs, sleds for pulling blocks, simple machines using ropes and pulleys, and simple mud brick ramps reveal the means for building pyramids, while *corvée* labor represented the most important element in the quarrying, transportation, and construction work for pyramids. The pyramids at Giza, for example, used 20,000- to 25,000-person crews. Graffiti reveal that the workforce contained crews of 2,000, who were further divided into groups of 1,000 that competed with one another. Tools included set squares and plumb bobs; copper drills and saws were used to cut stone using a slurry of water, gypsum, and quartz. Limestone is the primary stone used in building pyramids, with granite used on the casings. The Nile flowed closer to the pyramids in antiquity, making it easier to transport materials to the work site, such as limestone from Tura and the basic fuel, food, and animals needed for feeding and supplying the workforce. Blocks were moved using laborers pulling sleds over timber-paved roadways and lubricated alluvial mud to reduce friction in the movement of heavy loads.

The complex and massive level of organization required for building pyramids helped to unify and consolidate state power during the Old Kingdom. Individual pyramids were endowed with people, land, and produce to support each royal mortuary cult in perpetuity, while many new towns and farms were

funded through pyramid construction, making them a principal economic driving force in Ancient Egypt. The brilliance of the pyramids, reflecting the sun off their limestone casing, symbolized more than simply the necropolis for dead kings and facets of ancient Egyptian religion. The wonder associated with the pyramids has inspired subsequent visitors, from New Kingdom Egyptians, Greek and Roman travelers, and more recent tourists, giving rise to diverse theories concerning their origins and functions, including such unfounded theories as otherworldly origins. This subsequent fascination with Egypt (Egyptomania) has also given rise to modern reconstructions, such as at the Luxor casino in Las Vegas and the entrance pyramid at the Louvre. It is partly the man-made nature of the pyramids, their immense size, and the implied unity of the Egyptian state and purpose behind them, that continues to inspire visitors.

QING, THE LAST DYNASTY OF CHINA

The Jurchens (“Nuzhen” in Chinese pinyin romanization) were a Tungusic people who inhabited parts of northeast China and North Korea. Around the 11th century, part of the Jurchens migrated to the Yellow River basin. Those who remained were made up of three divisions: Haixi, Jianzhou, and Yeren. In the early 17th century, the remaining Jurchen tribes were unified under the leadership of Nurhachi (1559–1626). He organized them into “Eight Flags,” which were at once both an administrative system and a military confederacy. In times of war, then, the men readily and easily formed companies and battalions. Otherwise, they lived as trans-humans, engaged in pastoralism and small-scale gardening. Nurhachi was their leader and the supreme commander of the confederacy.

In 1616, Nurhachi founded an empire at Mukden (Shenyang) and proclaimed himself emperor. In one sense, this was the birth of the Qing Dynasty, though not yet in name. At the same time, the ruling class of the Ming Dynasty (1368–1644) grew increasingly corrupted. Nurhachi seized this opportunity to cut ties with his former liege, the Ming emperor. Active preparations were made for invading the Ming territories by Nurhachi and his Eight Flags, and a full-scale assault was launched in 1618.

In 1626, Nurhachi died of a serious wound inflicted in the battlefield. His son Huang Taiji (1592–1643) succeeded to the throne and continued the military operation relentlessly. By then the Jurchen army had grown into 24 “Flags,” thanks to the addition of eight Mongol Flags and eight Han Flags. It scored significant military successes against the Ming troops during the following decade. In 1636, Huang Taiji renamed

his empire “Qing,” which went down in history as “Manchu Qing.” Subsequently the Jurchens came to be known as the Manchus, of the Qing Dynasty.

At the time of Manchus’ aggression, the Ming Dynasty was also under siege from within, especially from the peasant uprisings led by Gao Yingxiang (?–1636), Li Zicheng (1606–1645), and Zhang Xianzhong (1606–1647). To deal with the imminent threat of peasant uprisings, the Ming government had to withdraw its troops from the north. But other than leaving the borders more vulnerable, this measure did little to stop the drive of the peasant uprisings. The Ming Dynasty collapsed on March 19, 1644, when the peasant troops of Li Zicheng stormed into Beijing, and the Ming emperor hanged himself.

Soon, however, the Manchus army overpowered the peasant armies and took possession of Beijing. Emperor Shunzhi (1644–1661), who had succeeded Huang Taiji as leader of the Manchus, moved his court to Beijing from Mukden (Shenyang). With this, a new dynasty was born in Chinese history—the Qing Empire (1644–1911). But it took the Qing rulers several more decades to subjugate the resistance movements put up by the remnants of the Ming loyalists who remained in the south and in Taiwan.

Although most of the country was conquered by now, there were still serious challenges for the Manchu rulers. The Manchus were greatly outnumbered by the Hans, and the empire was vast. For the purpose of maintaining internal cohesion and political stability, many Han administrative and military talents were employed. A number of Chinese ways and customs were adopted, and communication between the Hans and Manchus was encouraged, even though intermarriages were forbidden.

The reign of the Qing Dynasty involved a total of 12 emperors, some of whom were very able. Under

Emperor Shunzhi, for example, the Qing Dynasty was swiftly consolidated. While he was effective, a number of his successors were extraordinary. Among them was Emperor Kangxi (1661–1722), a great ruler who is remembered for his visionary policies. Kangxi managed to recruit many noted Han scholars into his service, a feat that positively changed the sentiment and attitude of the majority of the Hans toward the Qing rulers.

Emperor Qianlong, (1736–1795), the grandson of Emperor Kangxi, was another great ruler. During his reign, the Qing Dynasty reached its zenith in terms of power and wealth. A series of military conquests brought the territorial expanses of China to a historical high. Moreover, he was a man of letters. After a reign of 60 years he retired in 1795, leaving the throne to his son. Approximately 150 years later, the Qing monarchy had come to be regarded as a legitimate possessor of the Mandate of Heaven, or at least one that was ruling on a divine commission.

Peace at last prevailed. As long as the economy was thriving, people seemed to be contented. Literary traditions flourished and culminated in the composition of great novels and dramas. However, the peace proved to be the calm before a tumultuous storm. A population explosion ensued. Increasingly, it led the carrying capacities of land to be overtaxed, and the people grew restless. A revolt led by the religious sect called the White Lotus Order erupted in 1796. The insurrection spread like wild fire among the discontented poor and lasted into the beginning of the next century. The suppression was bloody and effective, but there was no end to the trouble in sight.

The 19th century was a time of continual unrest, during which the Qing Dynasty started to deteriorate. First there was the Opium War (1840–1842), which exemplified a collision of cultures and philosophies. On one hand, there was the deep-rooted Confucian tradition that had reigned supreme in Chinese thought and life for over 2,000 years. On the other hand, there was the European ideology of progress and liberty. This initial conflict between the two civilizations was to last for more than a century.

The immediate issue of the conflict was trade. Large quantities of opium were shipped and smuggled into China through the southern port of Guangzhou (Canton). It was extremely lucrative to the British but did great harm to the Chinese society. Seriously alarmed by the debilitating effects of this drug, the Chinese authorities decided to ban opium

trade in 1838. A high government official named Lin Zexu (1785–1850) was sent to Guangdong with the authorization to prohibit the bootlegging of opium on the penalty of death. In June 1839, a great amount of opium was seized from British merchants and then burned. Approximately 4,000 British troops appeared off the shore of Macao in June 1840, and the Opium War commenced.

The war eventually ended in 1842, when the Qing government was forced into signing the Nanjing Treaty. In addition to the payment of a huge indemnity, Hong Kong was ceded to the British for 99 years, five coastal ports were opened to foreign trade, and extra-territorial rights were granted to the British in China. Soon, other Western powers followed suit and demanded similar treaties and concessions.

Not only was China bogged down in the quagmire of humiliation and deprivation caused by a series of treaties with Western powers, but rebellions mushroomed as well. The one with the greatest momentum was known as the Taiping (Heavenly Peace) Movement. It was headed by Hong Xiuquan (1812–1864), a scholar-priest whose theology combined Christian notions with traditional Chinese values. By 1851, the movement had spread far and wide, drawing into its rank and file millions of poverty-stricken peasants and craftsmen who were suffering in the wake of the Opium Wars. The rebellion army sent the government troops fleeing in southern and central China. After Nanjing was captured, Hong set up the “Heavenly Peace Kingdom” (1853–1864).

As the cornerstone of the Chinese ruling elite, the scholar-gentry looked askance at the Taiping Movement. Many of its members proceeded to organize militia units in the name of local security and self-defense. Their military tactics and maneuvers were so successful that official recognition soon followed, elevating the militia forces to the spearhead of the Qing army against the rebels. The most prominent of the gentry-militia leaders was Zeng Guofan (1811–1872), a graduate of the civil service examinations who commanded a large following of scholarly and military talents, talent such as Li Hongzhang (1823–1901) and Zuo Zongtang (1812–1885). Zeng played a pivotal role in suppressing the Taiping Movement and other rebellions of the time.

Zeng Guofan and Li Hongzhang reasoned that the European countries were strong because they had modern science and technology. A number of measures were initiated in order to salvage the traditional

social system and institutions by emulating the Western approach to modernization while discarding its ideology of democracy and individualism. These self-contradictory efforts were doomed from the very beginning, and the country continued its downward spiral. Between 1894 and 1895, China lost its war with Japan over Korea. As a result, Taiwan was ceded to Japan, whereas Korea, once a protectorate of China, was declared to be independent. In 1910, an emboldened Japan reduced Korea to one of its colonies, in defiance of its agreement with China.

The dramatic decline of China led its intellectuals to search for ways of reinvigorating the nation. In a historic memorial to the imperial court, Kang Youwei (1858–1927), Liang Qichao (1873–1929), and others vehemently called for reforms. The reformists found an ally in the young emperor, who granted an audience to Kang Youwei in 1898 and was persuaded by him to introduce sweeping changes. Before long, however, the conservative force led by Empress Dowager Cixi (1835–1908) stepped in to nip the reformist agenda in the bud. The young emperor was stripped of power, and some reformists were ruthlessly executed. The Reformist Movement, which had lasted only a hundred days, was put to rest.

The 1900 Boxer Movement grew out of the local militia in Shandong and Shanxi, whose creed was to help the Qing government fight whatever was foreign. The Boxers were primarily peasants who saw foreign aggressions and influences as the root cause of China's deepening crisis. Their activities received tacit sanction from the authorities, but there were times when the xenophobic sentiments of the Boxers went beyond control, hence the government's ambiguous attitude toward them. The high point of the rebellion occurred in 1900, when the Boxers were summoned to besiege the foreign legations in Beijing. It triggered the invasion of an international contingent of troops from Britain, America, Japan, Russia, Germany, France, Italy, and Austria. The siege was lifted, but in the heat of the moment, some of the imperial palaces were looted and burned by the allied troops, inflicting great losses on China's cultural treasures and artifacts.

Entering into the 20th century, the Qing Dynasty was the ghost of what it used to be: corrupted, demoralized, servile to foreign extortions, out of touch with reality, and detested by its own people. A revolution was in the air, drawing its inspiration primarily from the teachings of Sun Yat-sen (1866–1925), a prominent leader who called on the Chinese

to overthrow the Qing monarchy and institute a political system that advocated “nationalism, democracy, and livelihood of the people,” known as the “Three Principles of the People.” On October 10, 1911, an armed revolt in Wuhan set off the revolution that quickly toppled the Qing rule, the last dynasty of China. Sun Yat-sen was elected the first president of the Republic of China.

The Quechua are the most widespread indigenous group of the Americas, with some ten million spread across Peru, Bolivia, and Ecuador (there known as *Quichua*), and smaller numbers in Argentina, Chile, and Colombia (there known as *Ingano*). Quechua speakers outnumber speakers of all other indigenous languages in South America combined, due in part to Quechua's status as the administrative language of the Inca Empire (*Tawantisuyu*), which at the turn of the 16th century covered much of western South America. Various Quechua dialects were quite widespread even before the Inca expansion, which was itself relatively short lived (c. 1438–1532); many Quechua-speaking communities are probably the descendants of peoples conquered by the Incas, rather than of the Incas themselves. Although the Inca Empire was toppled, and the indigenous population decimated by the European invasion and subsequent epidemics, the Spanish conquerors, rather than using their own language, also found Quechua to be a useful administrative language in their Andean colonies, and extended its use even beyond the boundaries of

the Inca Empire. Nevertheless, modern-day Quechuas are strongly ideologically associated with the Incas, and this link is often stressed in ethnic revitalization movements and other forms of political discourse.

The Incas are famed for their achievements in astronomy, architecture, resource management, medicine, and statecraft. A network of over 20,000 km of stone-paved roads connected their empire, and their agriculture was based on an extensive system of terraces and irrigation works. The masonry of their cities and ceremonial centers, of which Machu Picchu is the best-known example, is extraordinary even by modern standards; granite blocks weighing several tons are fitted so closely that a knife blade cannot enter between them. Although they knew neither writing nor the wheel, they were one of the most technologically advanced societies of their time. A complex system based on colored and knotted strings, known as *quipus*, was used by the Incas for record keeping.

As colonial subjects, the Quechua were dispossessed of their lands, enslaved, and frequently massacred during (or in retaliation for) indigenous uprisings. Although the Andean countries gained independence from Spain in the early 19th century, this did little to improve the lot of the indigenous majority, whose new masters—European-descended *criollos* born in the New World—were often even harsher than the old. Not until the 20th century were indigenous Andeans granted citizenship in their own lands, and even today they constitute the most impoverished and marginalized sectors of their respective nations. Although today there are small but significant numbers of self-identified Quechuas in academia, business, and government, social mobility has tended to be accompanied by cultural assimilation.

It is difficult to characterize the modern-day Quechua as an ethnic group, because the term covers several different peoples and languages spanning several countries. By no means do these constitute a single organized polity, despite significant cultural similarities and a shared historical trajectory. Many Quechuas have left their ancestral homelands in search of wage labor in the cities; Lima, Peru's coastal capital, now contains one of the largest demographic concentrations of Quechua speakers, and there are significant numbers in Argentina, Europe, and the United States as well. Within their home countries, Quechuas have sometimes achieved sufficient political organization to challenge state power, as in Ecuador's popular uprising of January 2000. Pan-Quechua unification is held out as a goal by some indigenous activists, but is unlikely given the current political reality of the region.

RADCLIFFE-BROWN, A. R. (1881–1955)

Alfred Reginald Radcliffe-Brown was a British social anthropologist who was responsible for developing the school of thought known as structural-functionalism. Born near Birmingham in England on January 17, 1881, Radcliffe-Brown's childhood was marred by a long battle with tuberculosis. Radcliffe-Brown enrolled in Trinity College in 1901 where he met and studied under anthropologists W. H. R. Rivers and Alfred Haddon. Both anthropologists instilled ideas about the importance of field research and its necessity for carrying out cross-cultural comparisons. These ideas would eventually become the hallmark of Radcliffe-Brown's research.

Radcliffe-Brown conducted fieldwork in the Pacific among the Andaman Islanders from 1906 to 1908 as part of his thesis research. While completing his fieldwork, Radcliffe-Brown began to read the work of French sociologist Émile Durkheim. Durkheim's ideas about the structure of social relationships would have a profound effect on Radcliffe-Brown and would influence his development of structural-functionalist ideology.

From 1910 to 1912, Radcliffe-Brown carried out fieldwork among various aboriginal tribes of Australia. A distinct focus of this research was kinship and its relationship to social structure. Two important volumes resulted from this fieldwork: *The Social Organization of Australian Tribes* (1931) and *Structure and Function in Primitive Society* (1935).

In addition to being a meticulous field researcher, Radcliffe-Brown was a distinguished lecturer at the University of Capetown (1920–1925), the University

of Sidney (1925–1931), the University of Chicago (1931–1937), and Oxford University (1937). At Oxford University, he also served as the first president of the Association of Anthropologists.

Throughout the latter part of his life, Radcliffe-Brown continued to pursue research on the social structure of primitive groups. Following World War II, Radcliffe-Brown set up research projects in Africa and Australia. He also conducted field research in South America. Radcliffe-Brown died in England in 1955 after suffering from pneumonia.

Radcliffe-Brown's major contribution to the field of anthropology was his development of the school of thought known as structural-functionalism. Drawing heavily from the work of Émile Durkheim, structural-functionalism teaches that the primary function of society is to maintain social structure. As a result, a complex system of social relations and social institutions develop that have primacy over culture. Within the society's social structure, the individual has little or no importance—rather, it is the society that dictates the structure and organization of the group.

Structural-functionalism focused on the interrelatedness of different institutions (i.e., economic, kinship, religious, political, etc.) to explain the social norms. Questions asked of individuals during fieldwork were structured to determine the interrelatedness of the various aspects of society and the extent to which different aspects of society influenced each other.

 RADIN, PAUL (1883–1959)

Paul Radin worked as an anthropologist in North America and specialized in Native American groups. His field was the ethnology of religion and mythology, as well as the ethnography of Native Americans.

Radin spent his early childhood in New York City, but was born in Poland on April 2, 1883. In 1902, he graduated from City College with his bachelor's degree and then went abroad briefly. After returning to the United States, he studied under Franz Boas at Columbia University. In 1911, he graduated with a PhD in history and anthropology.

An accomplished linguist, Radin described multiple Native American languages and attempted to demonstrate their unity. He advanced culture-personality studies and a historical model of society that synthesized many facets of social studies including religion, philosophy, economics, psychology, and social structure.

Radin's career was varied. He worked on the geological survey of Canada as a field anthropologist and took several teaching positions; California (Berkeley), Chicago, and Cambridge stand out among the list, but there were several more. His last teaching post was at Brandeis University, where eventually he was made head of the anthropology department. Radin advocated viewing primitive cultures as different from their modern counterparts not in kind, but in degree; that is to say, primitive human responses to the difficulties of life were complex but appropriate and comprehensible. He was not convinced that moral awareness was capable of progress, or that the moral awareness of primitive humans was all that different from that of modern humans. He studied intensively the religions, languages, and folklore of Native American cultures.

Radin began his fieldwork with the Winnebago (starting sometime in 1908) and also studied the

Ojibwa and the Wappo, among others. It would be the Winnebago, however, that would captivate Radin throughout his career. He wrote *The Winnebago Tribe* (1915–1916) and went on to publish texts detailing and analyzing nearly every facet of Winnebago culture. Radin made extensive use of autobiographical documents and reports in his studies, which is apparent in several of his publications, especially *The Autobiography of a Winnebago Indian* (1920; retitled *Crashing Thunder*, 1926) and *The Culture of the Winnebago: As Described by Themselves* (1949). He focused often on the individuals of a culture rather than the culture as a whole; for example, in *Primitive Religion* (1938), he proposes that the religiosity of any individual is directly related to the inclination and intelligence of that individual—ranging from indifferent to profound—in any given culture. Religiosity, then, is not a product of culture but the natural predisposition of the individual.

Radin's work attracted attention from various prominent intellectuals such as Swiss psychoanalyst C. G. Jung and the famous philosopher of education John Dewey. Radin published a number of important works during his career including *The Genetic Relationship of the North American Indian Languages* (1919), *Primitive Man as Philosopher* (1927), *Method and Theory of Ethnology* (1933), *Primitive Religion* (1938), and *The Road of Life and Death* (1945). Radin died on February 21, 1959.

 RAMSES II

Ramses II, also called Ramses the Great, was the third king of the 19th Dynasty of Egypt. He reigned for 67 years, from approximately 1290 BCE to 1223 BCE.

Ramses II brought Egypt to its height of prosperity and power. He was the son of Seti I (Sethos I) and Queen Tuya. Ramses acted as prince-regent during Seti's reign and succeeded the throne after his father, even though he was Seti's second son. Ramses was a charismatic leader who is most renowned for his many building projects, which include the temples of Abu Simbel with their colossal statues, the completed hypostyle hall at Karnak, and the Ramesseum, a mortuary temple at Thebes. He also completed his father's temples at Abydos and Luxor. During his reign, he moved the capital from Thebes to Piramesses ("House of Ramses"), which he built in the eastern delta of the Nile to expedite his campaigns against the Hittites in Syria. Piramesses possessed what was probably the largest stable in existence at the time. His military exploits ranged from Nubia and Libya to Syria, maintaining Egyptian borders to their greatest extent.

The Egypto-Hittite conflict over territory in Syria began during the reign of Seti I. The stalemate that existed between the forces of Seti I and Muwatillis of Anatolia was extended to Ramses. Muwatillis met the armies of Ramses at the famed battle of Qadesh, which was considered the turning point in the conflict with the Hittites. Ramses's armies were nearly overwhelmed, but through his brilliant leadership and innovative strategy, he was able to turn the battle and escape defeat. Losses were great on both sides. It was not a decisive victory in the true sense of that word, as Ramses did not actually take Qadesh. The battle of Qadesh is documented on the walls of temples at Abydos, Karnak, Luxor, Abu Simbel, and the Ramesseum. There are at least 13 surviving accounts of the battle, making it probably the earliest detailed account of a battle in ancient history. Tensions between the Hittites and Egyptians continued for another 16 years. Mursilis III succeeded Muwatillis briefly, but it was with Hattusilis III that peace was eventually established between the two countries through what is the earliest known surviving state-to-state peace treaty in recorded history. Originally engraved on a silver tablet, copies were made and kept in each country. The treaty was also recorded on stelae at the Karnak temple of Amun and the Ramesseum. Peace endured between the Egyptians and the Hittites of Anatolia throughout the rest of Ramses's reign. The two royal families exchanged letters and presents. Later, Ramses II married two Hittite princesses, in his 33rd and 37th regnal years.

Ramses II had a very large family, with over 100 children. His primary wives were the famed Nefertari, who was his first and favorite, and Isisnofret, who bore Ramses's successor, Merneptah, his 13th son. Ramses outlived many of his sons, including Sethirkhepeshef and Khaemwaset.

RAMSES II

Ramses II, known to Egyptians as simply Ramses the Great, was probably the most powerful of the Egyptian pharaohs. His reign covered two-thirds of the 13th century BCE and marks the peak of Egypt's power. Among his many accomplishments were the building of many temples, fathering 100 children, and bringing peace to Egypt. He is credited with negotiating the first recorded peace treaty in history, between Egypt and its perennial rivals, the Hittites. Ramses first married a Hittite princess, then negotiated the peace treaty.

However, Ramses II's most significant effect on anthropology may have come to light when tobacco was discovered in the bandages of his mummy. In 1976, Dr. Michelle Lescot of the Natural History Museum in Paris found a plant fragment within the fibers of the bandages. Examining it under a microscope, she was amazed to find it was tobacco.

She repeated the tests over and over, with the same result. The significance of the discovery lies in the fact that there was thought to have been no contact between Egypt and the New World at the time of Ramses. However, tobacco grew only in America and was supposedly unknown in the eastern hemisphere until it was imported into Europe after Christopher Columbus was introduced to it during one of his voyages.

The chief curator at the Cairo Museum, Nasri Iskander, believed the tobacco had been dropped from the pipe of an archaeologist who had examined the mummy. Dr. Lescot extracted new samples from the abdomen of Ramses II while others photographed the process. These samples also contained tobacco. For a number of years, this evidence was ignored. However, in 1992, Dr. Svetla Balabanova, of the Institute of Forensic Medicine in Ulm, Germany, tested the mummy of Henut-Tawy. Nicotine and cocaine were found. After her findings were confirmed by three other labs, she published a paper on the phenomena. To her surprise, scientists responded with rage and she was condemned as a fraud. Balabanova then tested tissue from 124 mummies. A third of them tested positive for nicotine and cocaine.

Dr. Rosalie David, Keeper of Egyptology of the Manchester Museum in England, believed the test results were quite impossible and decided to do her own tests. She tested the German mummies, then the ones in her own museum. To her amazement, they contained traces of tobacco. So Dr. Balabanova's work had been validated.

Scientists are still trying to determine whether there was trans-Pacific trade in the days of the Egyptian pharaohs, or if perhaps there were once some sorts of tobacco and coca plants that grew in Egypt, then later became extinct.

— Pat McCarthy

people's access to economic resources, sociocultural power, and status. As stated in *Cultural Anthropology* (2004), "Rank societies do not have very unequal access to economic resources or to power, but they do contain social groups with unequal access to prestige. Rank societies, then, are partly stratified." The most complex ranking systems are found in Polynesia.

Status (or prestige) refers to a social position with a distinction usually made between "ascribed" and "achieved." Ascribed status is assigned, often on the basis of birth, with age and sex being important markers and with some societies using perceived "race" and ethnicity to assign status. Achieved status is attained through the behavior of an individual, often in terms of occupation and skills and actions. The king of England is an ascribed status; a professor of anthropology is an achieved status. These types of statuses may, however, intermix; we now have third-generation anthropologists, and the line of succession in some royal families is in question.

Membership in social groups can also be ascribed or achieved. In ascribed groups, membership is acquired at birth and is non-voluntary. Assembling people into multipurpose groups on the basis of ascribed categories is one of the chief principles of group formation in nonindustrial societies. The most common types of ascriptive multipurpose groups are also based on age, sex, ethnicity, and kinship. Groups based on achievement are usually called voluntary groups or special-purpose groups. These voluntary associations are found less often in nonindustrial societies, and when they are found, such as hunting groups, they are quite temporary.

Typically, social groups are ranked, not individuals, though the literature often uses the position of chief as an example. More accurately, the chief belongs to a social group that is ranked high in status. And the position of chief is at least partially hereditary. Typically, each kin group has its own unique rank in relation to the other kin groups, and within each kin group, individuals are ranked by genealogical seniority. In any case, the chief is treated with deference, as has been noted in most ethnographies from Oceania, such as Raymond Firth's excellent study in the 1920s of the Tikopia. People may have to keep their head lower than that of the chief, and chiefs may receive gifts and have substantial storehouses, but these surpluses are usually given away in public feasts. And the chief cannot order people to work or to give him gifts.

RANK AND STATUS

The most common use of the term "rank" in anthropology is to designate one type of society among three (the others being egalitarian and class) regarding the

Citing a study of Ifaluk by Laura Betzig (1988), which found that the chiefs seem to be economically better off than the commoners, Carol R. Ember and Melvin Ember caution, “Is this true in other societies conventionally considered to be rank societies? We do not know. . . . But rank societies may not have had as much economic equality as we used to think.”

— Robert Lawless

RAPA NUI

Rapa Nui is a small (160 km) remote subtropical island in the South Pacific Ocean, 3600 km west of Chile, the nation of which it forms a part, and 1900 km east-southeast of Pitcairn Island, the nearest inhabited island. It is known to outsiders as Easter Island (Isla de Pascua in Spanish), so named by Dutch navigator Jacob Roggeveen after his visit to the island on Easter in 1722. Rapa Nui is the locally preferred name, used since the 19th century, which also refers to the people and their language. Although its large monolithic *moai* stone statues are widely recognized, substantial mystery still surrounds the origins and development of the people who erected these monuments. Reconstructing the history of migration, adaptation, innovation, contact, and survival has been the focus of studies to which archaeology, linguistics, biological anthropology, ethnology, ecology, and related disciplines have all contributed.

Oral histories tell of an original settlement of people arriving from the west from a land called Marae Rega or Marae Toe Hau, led by Hotu Matu’a—Great Parent—the first *ariki* (chief) of the island. The Rapa Nui have been considered culturally and linguistically Polynesian since their first contacts with European visitors. In the 1940s, however, Norwegian explorer

Thor Heyerdahl hypothesized that the island was first settled from South America, before Polynesians arrived. As evidence, he pointed to the sophisticated and large-scale stone work of the *ahu* (ceremonial platforms), the presence of sweet potato (*Ipomoea batatas*) and other native South American plants, the path of ocean currents, and other ethnological and linguistic evidence. His much publicized Kon-Tiki raft expedition of 1947 attempted to demonstrate the plausibility of this theory. Most experts today tend to discount the South American origins of the stonework, but many acknowledge the possibility of contact.

Early studies relying primarily on linguistic and archaeological data estimated that the island was likely settled from Eastern Polynesia before AD 600 or as early as AD 400. More recent research based on further analyses in archaeology, linguistics, biological anthropology, and experimental voyaging has, however, led researchers to propose later settlement dates around AD 600–1000. Earlier hypotheses regarding a direct settlement originating from the Marquesas have also been revised to favor settlement(s) from the Mangareva-Pitcairn-Henderson area. Yet another hypothesis postulates that settlers may have arrived from the Marquesas via South America, and may have brought back the sweet potato.

The Rapa Nui are a testament to the remarkable achievements and migrations of the descendants of proto-Austronesian speakers originating from southern China, who over the last 5,000 years—including 3,000 years in Oceania—migrated and settled an area spanning 28,000 km on an east-west axis, with Madagascar off the east coast of Africa at its western end and Rapa Nui at the eastern end. The successful colonization of new Pacific islands and the subsequent development of complex societies depended not only on their skills as navigators but also on subsistence strategies, especially regarding food production in the sometimes limited physical environment of their new homes. Hotu Matu’a is said to have brought food crops and introduced them to the island, including pigs, chicken, bananas, taro, yams, sugar cane, ti, and even sweet potatoes. While most researchers disagree with Heyerdahl, contact with South America is considered a possible factor in the cultural development of this island society. For example, the introduction of the sweet potato is considered a major factor in agricultural intensification, which the archaeological evidence shows to have been widely adopted on the island after AD 1200.

Some time after the initial settlement, the islanders began to build sacred sites with stones and to carve statues to represent their ancestors. The natural forest woods they found on the island would have been important for their construction and transportation. Beginning around the 11th century, the construction of *moai* intensified greatly, and the scale of constructions grew and became more complex. According to legend, as he lay dying, blind and ill, Hotu Matu'a divided the island among his six sons. Social organization then followed a conical clan (or ramage) system, a typical pattern in Polynesian chiefdoms with hierarchically ranked unilineal descent groups. In each descent group, a paramount chief (*ariki mau*), the senior male in direct line of patrilineal succession from Hotu Matu'a, possessed power (*mana*) derived from gods. Each patrilocal segmentary descent group (*mata*) occupied a specific estate (*kāinga*), which included both coastal and interior zones demarcated by stone cairns (*pipihoreko*) and protected by local estate spirits (*akuaku*). Local descent groups built *ahu*, usually by the coast, and erected *moai* above them with their backs to the ocean and overlooking the villages they faced. Each *moai* represented an eponymous ancestor of a local segment of the descent group. Patrilocal extended families (*paenga*) formed the basic economic units and were engaged in reciprocal and hierarchical economic and social networks with others in the lineage (*ivi*). By the 15th and 16th centuries, the island was subdivided into 10 or 11 polities

occupying all of the island, organized into two political confederacies: the *Tu'u 'Aro* (or *Ko Tu'u 'Aro Ko Te Mata Nui*, "the Greater Mata"), who occupied the north-eastern half and were named after Hotu Matu'a's eldest son Tu'u Maheke, and the *Tu'u Hotu 'Iti* (or *Ko Tu'u Hotu 'Iti Ko Te Mata 'Iti*, "the Lesser Mata"), named after his youngest but favorite son Hotu 'Iti. Comparative works on pre-historic Polynesian societies consider Rapa Nui to be similar to that of Mangaia, and less stratified than those of Hawaii, Tonga, and

Tahiti, but more stratified than Tikopia, Pukapuka, Ontong Java, and Tokelau. The high levels of segmentation, stratification, division of labor, and the ability to mobilize pan-island cooperation and exchange networks are evident in the approximately 300 *ahu* and 900 *moai* left on the island, which involved the construction and transportation of large stone figures from Rano Raraku quarry and their erection on top of the platforms. Competition between local groups is believed to have led to a race to create ever-larger platforms and statues. The largest *moai* to be erected on *ahu* weighs an impressive 80 tons and measures 10 m in height; 12 m once the red scoria topknots (*pukao*) had been placed on top. The population is believed to have grown to between 7,000 to 10,000 by the 16th century. The period of great constructions, rising prosperity, and population growth was followed by a period of warfare and decline. Oral traditions tell of the outbreak of internal strife and endemic warfare among the descent groups, leading to the collapse of the process of *moai* making in the two centuries before European contact. When Captain James Cook visited the island briefly in 1774, he found that many of the statues had been overturned, and he noted that the islanders seemed rather impoverished for a people who had once erected such impressive monuments. He also noted the terrible condition of their canoes and the island's lack of forest. Pollen analysis indicates that the island had been initially well forested, but forest pollen declined to its lowest measured

values circa AD 1400. Sometime after the 15th century, the island had become largely or completely deforested.

What led to the abrupt collapse of a once prosperous society? Human activities and competition for resources between descent groups were likely the major cause of the decline of the forest and the overexploitation of other natural resources. This, in turn, led to the decline of monumental constructions, increasing warfare, and, in Malthusian fashion, to population decline. This interpretation has led researchers to view the history of Easter Island as a warning of the perils of natural resource overexploitation.

In the 15th century, a new politico-religious subsystem emerged from this period of turbulence. The new system, referred to as the Birdman (*tangata manu*) Cult, emerged with Orongo (the southwest rim of the caldera Rano Kao) as a pan-island site of annual competitions and ceremonies. Each descent group chose a representative (*hopu manu*) each spring who would have to swim in dangerous waters to the nearby islet of Motu Nui and return with an undamaged egg of *manutara* birds (sooty tern). The chief of the winning competitor's descent group was conferred the status of *tangata manu*, or the ruler of the island, for one year, as empowered by the creator god *Make Make*. The Orongo ceremonial village is today still full of rock art depicting *tangata manu* and other figures, and its stone structures were built to mirror the two political confederacies. The emergence and development of the Birdman Cult reflects a transition in the prehistoric Rapa Nui society, where the traditional hereditary, sacred power of the *ariki mau* diminished, yielding increasingly to achieved status competition and a political system ultimately dominated by a warrior class (*matato'a*). Although the importance of the *moai* and *ahu* for the islanders had declined before their contact with Europeans, the island seemed to have preserved some aspects of traditional social organization surrounding the *ariki* nobility system into the mid-19th century.

Another of the so-called “mysteries” of Rapa Nui is *rongorongo*, the only indigenous script known to

Source: © iStockphoto/Brendan O'Boyle.

have been used in Oceania before the 20th century. Today there are 25 known surviving wood tablets bearing *rongorongo* inscriptions scattered in museums and institutions around the world, and numerous researchers have been working to decipher them. Oral histories tell of *rongorongo* specialists (*tangata rongorongo*) who chanted as they read the inscription on the tablets during the annual birdman competitions and ceremonies. One hypothesis locates the development of *rongorongo* after 1770, when a Spanish expedition briefly stopped at the island and ceremoniously proclaimed the island to be Spanish by presenting an official deed signed by Spanish officers. While this suggests that writing may not have been invented on the island, the *rongorongo* system was clearly created by the Rapa Nui as an indigenous elaboration.

In the mid-1860s, Blackbirders, or slave raiders, abducted or recruited an estimated 3,000 Polynesians

and a few hundred Micronesians to work in the state-run guano export plantations on the Chinch Islands off the coast of Peru. As many as 1,500 Easter Islanders were carried away in a dozen or so ships between 1862 and 1863. Many died under the harsh and unfamiliar conditions they encountered in Peru, and, tragically, the very few who were able to return to the island alive brought with them a smallpox epidemic that killed many more. From an estimated pre-raid size of 3,000 to 5,000, the island's population collapsed to scarcely 110 survivors in 1877. The population crash led to a disintegration of existing social organization, and a great loss of cultural knowledge of the island's traditions and rituals occurred as many elders and specialists perished. Further contact with outsiders had a significant role in further cultural changes for this devastated community. For example, the Catholic missionaries who stayed on the island shortly after the slave raid until 1871 led the community-wide conversion to Christianity and led the Rapa Nui to abandon the use of *rongorongo* and the Birdman Cult and other rituals. European planters who arrived in 1866 collaborated with the missionaries to have the Rapa Nui resettled near the Hanga Roa mission in order to develop the island commercially as a sheep ranch.

In 1888, Chile annexed the island in a naval mission led by Captain Policarpo Toro. During the first half of the 20th century, Chile established its authority over its colony primarily by delegating control to the fittingly named "Easter Island Exploitation Company," which leased the entire island as a private sheep ranch from 1895–1955 and forcibly confined the Rapa Nui to live and remain in Hanga Roa village, using the rest of the island for sheep grazing. Ethnological work by Katherine Routledge, the first anthropologist to reside on the island (for 16 months in 1914–15), recounts the living conditions of the Rapa Nui under company rule and the memory of the elders who had witnessed the functioning of society before the population crash. She was also witness to a short-lived 1914 rebellion against the company led by the prophet Maria Angata Veri Tahi a Pengo Hare Kohou, who had been trained as a catechist in Mangareva. Spanish-speaking administrators of the company—and, after 1935, the Catholic priest—acted as state representatives and mediators between the Rapa Nui and the colonial government.

Except for the attention of anthropologists and archaeologists, such as the 1934–35 Franco-Belgian expedition led by Alfred Métraux and Henri Lavachery and the 1955–56 Norwegian expedition with Heyerdahl and William Mulloy, Rapa Nui remained largely isolated from the world until the mid-1960s. Until then, an annual cargo ship had been the primary form of communication and transportation. In the 1960s, a campaign of civil disobedience led by Alfonso Rapu, a young teacher who had been trained in Chile, finally brought about the end of Navy rule, which had controlled the island since 1955. Responding to this movement, Chile established a local civil administration in 1966 and opened regular air travel from the capital of Santiago shortly after. The Rapa Nui were then, for the first time, granted rights to travel freely within and outside the island and to participate in electoral political processes, leading to the election of the first Rapa Nui mayor. The rapid integration of this community into the national and global economy in the years that followed has led to accelerated acculturation, intermarriage, and language shift from Rapa Nui to Spanish. At the same time, however, the Rapa Nui community has become actively involved in the development of heritage tourism and restoration projects of the archaeological patrimony, and have led a largely successful cultural revival movement.

The Rapa Nui's efforts to increase their local political and economic control over island resources was greatly enhanced by national democratization and decentralization initiatives that followed the 1989 end of Pinochet's military dictatorship. This has led to successful political campaigns to press the government for increased land rights and a transfer of decision-making power to islanders. Today the Chilean Congress is debating proposals to grant the island, with its current population of 3,800, a new form of administrative autonomy. Despite their often tragic history of contact with outsiders, the Rapa Nui represent a rather remarkable case of language and culture maintenance. If there has been one constant in the dramatic and eventful history of this small and remote island, it is the Rapa Nui people's amazing adaptability in the face of great odds.

most important resource, one which could have been a renewable resource. If they had practiced reforestation, some of the devastation that occurred could have been prevented. Certainly the story of Rapa Nui's demise has implications for modern society.

— Pat McCarthy

 RAPPAPORT, ROY (1926–1997)

Roy Rappaport, one of the leading ecological anthropologists of the 20th century, was born in New York City. He earned his undergraduate degree from Cornell University. In 1959 (at the age of 33), Rappaport enrolled at Columbia University where he studied anthropology under Marvin Harris, Harold Conklin, Margaret Mead, Conrad Arensberg, and Andrew P. Vayda. He claimed that the anthropologist who most influenced him was Gregory Bateson, whom he first met in 1968. It was Bateson who introduced Rappaport to systems theory and encouraged him to look at evolution and adaptation as informational processes.

Between 1962 and 1964, Rappaport conducted fieldwork among the Maring of Papua, New Guinea, primarily among the Tsembaga clan. His greatest contributions to ecological anthropology stem from his precise measurements of the activities of 204 Maring speakers during the summer of 1963. In 1964, Rappaport presented a paper, "Ritual Regulations of Environmental Relations among a New Guinea People," at the American Anthropological Association. The 1964 paper was published in the journal *Ethnography* and has been widely reprinted. This paper contains almost all of the ideas that were to occupy Rappaport's thought for the rest of his life. In 1965, Rappaport joined the anthropology faculty at the University of Michigan, where he taught for over 30 years.

Rappaport's 1966 doctoral dissertation was published as *Pigs for the Ancestors*. His goal in *Pigs for the Ancestors* was to go beyond the arguments of cultural materialism and functionalism to focus on the adaptive value of rituals in maintaining carrying capacity, the persistence of species, human nutritional well-being, and the frequency of warfare within small-scale

**RAPA NUI**

Rapa Nui is a classic example of a society that brought about its own downfall by unsound ecological practices. Several practices of the inhabitants of the island contributed to this downfall. Anthropologists have determined that the island was once heavily forested, mainly with palm trees. As the population of the island grew, more and more trees were cut down to make room for fields, where the people could cultivate crops to feed their growing numbers. Scientists speculate that the statues were moved from the quarry where they were carved to the coast by rolling them on huge palm tree logs. As they carved more statues, deforestation increased. Eventually all the trees were gone. Due to the fragile ecology of the island, they did not grow back.

The demise of the forest had more important consequences than rendering the people incapable of moving statues. They also had no wood with which to build canoes and were then restricted to the island. This made fishing difficult. Wind and rain washed away the soil, causing crops to fail. Many people starved, and scientists believe lack of food led to cannibalism on the island. The population of Rapa Nui had used up their

societies. *Pigs for the Ancestors* contains Rappaport's key ideas in human ecology and religion; most notably, what he saw as the occasional contradiction between "operational" and "cognized" environments. Rappaport emphasized that the "operational" environment—governed by the immutable laws of the physical universe—and the "cognized" environment—which he defined as "the sum of the phenomena ordered into meaningful categories by a population"—differed due to the fact that "cognized" environments are less bound by physical laws.

According to Rappaport, there are two universal aspects of ritual: (1) it constitutes an invariant sequence of acts and utterances (form), and (2) its participants must actually perform according to these invariant sequences. Rituals impose a standard of conduct that goes beyond the will of individual participants and constitutes the foundation of all convention. Ritual is the basic "social act." Ellen Messer has suggested that Rappaport spent the earlier part of his academic career documenting his ideas on human ecology and *how* ritual regulates environmental relations and the rest of his life trying to understand *why* ritual should order ecosystems and human life.

Always active professionally, Roy Rappaport served as chair of the Department of Anthropology at the University of Michigan and was president of the American Anthropological Association from 1987 to 1989. He was also elected to membership in the American Academy of Arts and Sciences. A highly committed, ethical, and engaged scholar, Rappaport advocated bringing anthropological findings to bear on social issues of the day. He served as a consultant for the state of Nevada on the advisability of storing nuclear waste at Yucca Mountain and was a member of the National Academy of Sciences Task Force dealing with the leasing of offshore oil rights. From 1991 until his death, Rappaport served as head of the Program on Studies in Religion (PSIR) at the University of Michigan. He regularly offered the course Anthropology 448/Religion 452: "Anthropology of Religion: Ritual, Sanctity, and Adaptation."

While heading the PSIR, Rappaport embarked on what was to become his last major study, published posthumously as *Ritual and Religion in the Making of Humanity*. *Ritual and Religion* is one of the most comprehensive anthropological studies of religion ever published. In it, Rappaport attempted to

establish a new set of categories for the study of religion and makes a strong case for what he saw as religion's central role in human evolution.

Polynesia is a geographical triangle in the Pacific Ocean with Hawaii, New Zealand, and Rapa Nui (Easter Island) as its three points. Starting about 65 million years ago, ongoing volcanic activity began forming the Cook Islands of Polynesia between Fiji and Tahiti. The resultant archipelago consists of 15 major islands, six of which are the worn emergent peaks of now-extinct volcanoes (Mauke, Atiu, Mangaia, Mitiaro, Rarotonga, and Aitutaki); islets, or Hotus; sand-cays on coral reefs; and atolls. Rarotonga is the largest and youngest of those volcanoes forming the Cook Islands. It is located almost 3,000 statute miles directly south of Kauai, the oldest major island of the Hawaiian archipelago. Radiometric dates of lavas indicate that Rarotonga started emerging during the Plio-Pleistocene Age, about 2.8 million years ago. Today, this dormant and eroded volcano has a core surrounded by Pleistocene sands and gravels.

Rarotonga is an elliptical island whose impressive prehistoric-like landscape consists of towering razor-back volcanic ridges of central mountains covered with rich tropical vegetation (sea winds keep Rarotonga

cool). This mountainous area is deeply dissected by steep valleys and numerous streams. The rich lowlands are studded with coconut and banana plantations. White beaches stretch along the southern shore of this pristine and peaceful island, but the distant roar of ocean breakers is a constant reminder of both the creative and destructive forces of nature.

One of the geological landmarks of Rarotonga is The Needle (*Te Rua Manga*), although this unique 300-foot rock outcrop is dwarfed by the higher igneous horizon of this volcanic island landscape. A short, pleasant hike inland along the Avatiu stream, with butterflies and ubiquitous mynah birds as companions, and then a long, strenuous climb up a steep, root-covered mud path will take the adventurous intruder through breathtaking forests of tropical greenery and, finally, to a close-up sight of The Needle in all its primeval splendor.

During the past few thousand years, Rarotonga may have welcomed to its shores many brave migrating peoples who came first from the Tongan Islands and then from all over the Pacific Ocean. Not surprisingly, the first discoverers of this island are remembered only through legends and myths.

Centuries ago, seafaring Māori warriors from the islands of Tahiti, Samoa, New Zealand, and elsewhere

navigated the ocean on rafts or in outrigger canoes. Using a canopy of stars as their compass, they voyaged throughout Polynesia, eventually discovering the Cook Islands and then the Hawaiian archipelago. No doubt these migrations helped to limit the detrimental kin intermarriages within small communities on these isolated islands.

After waves of early arrivals, the lofty mountains and fertile shores of Rarotonga welcomed their final and definitive visitors from Tahiti during the 13th century. These fierce but cunning Māori warrior clans settled in over 20 tribes, or *Iwi*, scattered throughout three geographical districts of the island. The Māori of Rarotonga are tall and robust, with black hair, dark eyes, and medium-brown skin. They have a friendly disposition, living close to the land and enjoying music and dance. For hundreds of years, Rarotonga was inhabited only by these nonliterate settlers, who explained their origin and interpreted this world in terms of magico-religious beliefs and an oral tradition.

Rarotonga legend has it that in 1350 CE, seven canoes full of Māori warriors from the Takitumu village set sail from the eastern Ngatangia Harbor for New Zealand. Actually, they would have had to finally depart from the southwest coast at the mouth of the Maungaroa Valley. Their goal, which they achieved,

was to colonize New Zealand. This historic site at Takitumu is now marked by seven symbolic stones.

Those ancient inhabitants of Rarotonga spoke a distinct Māori dialect that had evolved out of a pre-historic Eastern Oceanic language. Nevertheless, this dialect linked them to the other cultures of Polynesia. Today, however, this original Māori language is becoming lost to a modern dialect.

Mixing facts with myths and values, Cook Islands legends reflect both the social history and cultural heritage of the early Māori inhabitants. Unfortunately, the oral tradition that preserved these stories is on the decline. To date, only a few of those numerous tales have been recorded for posterity; many such legends may be lost forever.

Nevertheless, one can now read about the evil hag Katikatia, who enticed children into her Rarotonga cave and then ate them; the giant Tamangori of Mangaia, who also loved to eat human beings; those mighty warriors who stole Maru, the highest Rarotongan mountain, and sailed with it back to their flat island of Aitutaki; and the magical origin of the first Polynesian wild hibiscus tree from the grave of the old sage Papa Manu (and, consequently, the discovery of making fire by rubbing together two sticks from this 'au plant).

The ancient Māori of Rarotonga built an inland road (Ara Metua of Toi) around most of the island so that their dwellings, fields, human burials, and sacred places were protected from hurricanes and cyclones. Even so, periodic famines and frequent intertribal wars threatened their existence.

Māori communities had a sociopolitical hierarchy, with the warrior class positioned just below the royal family but above the common workers and slaves, who were taken prisoner in hand-to-hand warfare. Tribal members practiced exogamy and polygamy while acknowledging patrilineal descent. Land was the property of the tribe. Māori implements were made of stone, bone, or wood. Typical of tools from volcanic islands, adzes made from island basalt were used for cutting wood, for example, in the making of canoes. On Rarotonga, such tools were used more than 1,000 years ago. Weapons were made only of stone or wood, as these people never discovered metallurgy.

Food is of great value to the Māori, who practice terrace farming. As horticulturists, they plant yam, taro, kava, and the sweet potato, or *Kumara*. They also enjoy an island of beautiful flowering plants: hibiscus,

gardenia, bougainvillea, poinsettia, and the mountain orchid. Pigs and fish figure prominently in the Rarotongan diet. Swimmers in the bountiful ocean must beware of stone fish, reef shark, and the deadly cone shell *Conus geographus*.

The animistic Māori ancestors worshipped many gods. They believed that these gods took temporary residence in material emblems during magico-religious ceremonies, thus demonstrating the significant relationship between their artworks and their beliefs. Furthermore, both gods and human spirits could reside in fish, birds, insects, reptiles, and other life forms. Each god had magical power, or *Mana*, to adjudicate over particular things.

In this pantheon of spiritual beings, Tangaroa was the supreme god of all creation. As such, he was the lord of plants, fish, fertility, human behavior, and the weather. His image was present throughout most of the Polynesian islands, although in various forms. In fact, his carved statue was even secured to the front of fishing canoes for good luck. Today, the image of Tangaroa appears on the dollar coin of the Cook Islands.

At Rarotonga, both infanticide and cannibalism were customary until the introduction of Christianity in 1823. Revenge in times of war was the major motive for Māori cannibalism. Usually black-tattooed warriors partook of such sacrificial feasts, but the tribal high chief never ate human flesh and workers did so infrequently, for example, during times of famine.

These early Māori believed that after death, a person's immortal soul, or *Wairua*, went to reside in Te Reinga, a heaven located under the sea. All brave warriors could look forward to an enviable afterlife in the House of Tiki.

Interestingly enough, explorer James Cook never discovered Rarotonga. In 1789, mutineers from HMS *Bounty* were the first Europeans known to have seen this island. Twenty-four years later, Captain Theodore Walker merely sighted Rarotonga while sailing from Tahiti to Australia. But the following year, skipper Philip Goodenough went ashore to Avarua. In 1823, with his friend Papehia, the English missionary John Williams from Raiatea brought Christianity to Rarotonga. The Gospel was preached, Māori hymns were composed, churches and schools were built, and the first complete edition of the Holy Bible in Rarotongan Māori reached the island from England in 1852.

Some missionaries used fear, force, and unethical means to convert the Māori to Christianity; they also provoked wars and brought foreign diseases to the island. Nevertheless, most of the Rarotongans quickly replaced Tangaroa with Jesus and were even happy to abandon cannibalism. A former cannibal, the Rarotongan tribal high chief Tepou became one of the earliest converts to Christianity. In a relatively short period of time, Christianity took a firm hold. Today, the Takamoa Theological College at Avarua, founded in 1837, still prepares missionaries for religious work throughout the South Seas.

The coming of Christianity also resulted in the almost total loss of Māori beliefs and customs. The converts burned their wooden idols, discarded their weaponry, and forgot their oral tradition. However, more than 200 different archaeological sites have now been discovered, including over 70 *Marae* (special gathering places of magico-religious and sociopolitical significance to the early Māori) found on the southern slope of flat-topped Mt. Raemaru, in Maungaroa Valley. These numerous inland sites indicate that a much larger Māori population once existed on this island before the coming of Christianity. Today, Raymond Pirangi (himself a descendant of a tribal high chief, or *Ariki*) is painstakingly clearing the entrance to the lower Maungaroa Valley so that tourists and scholars may visit its archaeological sites and learn more about the ancient Māori culture.

Along the ancient inner road is the coral and lime palace of Pa, a high chief of the Takitumu tribe. Built above road level, this royal structure indicated the central place of this Māori settlement. The villagers themselves lived in rectangular coconut-palm-thatched houses that kept their occupants both cool and dry. Like early communities, these Takitumu people lived safely inland until the missionaries arrived and built a church on the outer road near the harbor. Only then did the converted natives abandon their own site and move to the coast.

Also of archaeological importance is the *Arai-Te-Tonga Mara*, which is located inland from Muri Beach and is over 200 years old. This special site of stones designates a place where worshipping Māori held feasts with offerings and rituals for the ancient gods. The largest stone is a basalt pillar from the island of Raiatea, linking the Cook Islands to Tahiti. Likewise, this site functioned as a royal court, or *Koutu*, where the investiture of a tribal high chief, or *Ariki*, took place. A community of huts and fields

once surrounded this sacred spot. About 10,000 people now inhabit Rarotonga, and its harbor town of Avarua welcomes tourists from all over the world. On Sunday, devout Rarotongans attend Mass or other religious services. Men wear white shirts and ties, while women dress in their finest black-and-white outfits with elaborate straw hats. The religious ceremonies include both thunderous songs of the Māori past and beautiful Christian hymns of today in an intense mixture of two cultures.

Tara'are, T. A. (2000). *History and traditions of Rarotonga* (R. Walter & R. Moeka'a, Eds.). Auckland, NZ: Polynesian Society.

Reciprocity is the state of mutually addressing the same attitudes or feelings as another. It indicates an equal exchange. This implies intersubjectivity and interaction not only between individuals, but also between groups. It may, therefore, be applied to many fields of social activity and has acquired special importance in psychology, education, ethics, politics, and law.

Although the quality of the reciprocal attitudes or feelings is neutral (there may be a positive or a negative mutual exchange), the term is most commonly used for sharing something considered to be positive.

Reciprocity is one of the first elements that contributes to a child's psychological, physical, and social development by the spontaneous imitation of the parents' attitudes, expressions, and movements. The feeling of reciprocal love between parent and child is one of the most important factors for the creation of an equilibrated individual personality. Besides the emotional flourishing it creates, it establishes a psychic environment of security and confidence, which is vital for young human beings and of crucial weight for their future evolution. On this basis of reciprocal confidence and goodwill is founded any other

successful educative relationship in the following years of the human life.

The “reciprocity of consciences” consists of sharing the same ideas, values, or points of view. It facilitates mutual empathy, the capacity of “putting oneself in the other’s place,” integrating the other’s sentiments and positions, and may thus create a sense of harmonious unity between individuals. In this sense, the Other becomes like “another Self,” an *alter ego*, who is felt at the same time as a distinct person and as a part of ourselves.

This kind of reciprocity is notably present between friends. Aristotle (384–322 BC) was one of the first thinkers who insisted on this point. In his ethical works, he considers the best kind of friendship to be the one that is founded on mutual affection, due to the virtuous character of both persons. Many centuries later, Michel de Montaigne (1533–1592) omitted the notion of moral value of the character from reciprocity in friendship—a human relationship for which he had a high consideration—putting it beyond any social conventions. He believes that true friends realize equality by the purest of all the different kinds of love. They love each other just because they are who they are, and this engenders all the pleasure of sharing. The reciprocity of feelings of love, accompanied this time by desire, is also the basis of the amorous relationship. Eros without response results in frustration and distress, which have too often been the subject of literature. The contemporary philosopher who has particularly valorized reciprocity as a central notion of his thought is Paul Ricoeur (1913–). Considering that the previous theories on self-definition and self-conscience, as well as on the foundation of ethical behavior, have stayed within the limits of egocentrism, he insisted on the definition of the self as a structure derived from “being together.” Self-esteem and respect of the Other manifest themselves in a reciprocity that may be conceived as a “symmetrical” relationship, as it doesn’t accentuate the role of the “I,” as opposed to “the Other.” Ricoeur proposes to replace the “I” with the “self” in our way of thinking, as a means of reestablishing the fundamental resemblance among persons: the other is a “self” as much as “myself,” and can also say “I.” Only a relation of reciprocity may establish the feeling of “being the same” as the other and create the sense of equality and friendliness among people. Even for each one of us separately, the maintenance of a stable identity (the continuous “similarity to oneself”) is

achieved, according to this thinker, thanks to a kind of “promise” given to someone who counts for us. Ethical behavior is therefore more than an “obligation”; it is a free mutual affectionate consent.

Reciprocity becomes extremely important for the ethical and legal relations among all members of a society. If the moral and social rights and obligations that guarantee the harmonious functioning of any human society aren’t mutually recognized and applied, the society can’t continue to exist.

The ethical attitude founded on the principle of reciprocity is expressed negatively in the Hebraic Talmud of Babylon (Shabbat): “Don’t do to your fellow man what you would detest he did to you,” and positively in the Christian New Testament (Luke 6:31; Matthew 7:12): “Do to others what you would have them do to you.” The Koran (Sura 109:1–6) also presents a mutual recognition of the right of everyone to have his own faith.

Just ethical behavior, according to the theories of Immanuel Kant (1724–1804), demands mutual “respect” for the Other, being seen as an end *in se*, that is, for what he is himself and not as a means to acquire something else.

The Declaration of Human and Citizen’s Rights, a product of the French Revolution (1789), advances that all men are born free and equal by nature and defines “liberty” as doing whatever doesn’t harm others: “the exercise of the natural rights of each man has no other limits than the ones which assure to the other members of the society the enjoyment of the same rights. These limits can only be determined by the law” (Article IV).

Reciprocity in the recognition of human rights, founded on the natural equality of all human beings, becomes then the decisive factor for the limitation of personal liberty.

The Universal Declaration of Human Rights, adopted by the United Nations in 1948, starts with the following article: “All human beings are born free and equal in dignity and in rights. They possess reason and conscience and should act towards each other in a spirit of fraternity.”

The notion of “fraternity” already accompanied those of “liberty” and “equality” in the well-known declaration of the French Revolution. Reciprocity in social life should, according to this point of view, not only refer to mutual respect but also be extended to a true “solidarity,” a kind of support like the one found among brothers and sisters.

There have been many different opinions concerning the reciprocity necessary for the proper functioning of human societies and the reasons why reciprocity is chosen.

Humans being by nature “social animals,” as Aristotle pointed out, some thinkers considered that it is by reasonable necessity that human beings, when they come to live together in a society, conclude a kind of “social contract,” a common agreement on what they will consider as “just” and “unjust,” on which the rights and obligations, as well as the whole legislation of their particular society, will be founded (see, for example, the theories of John Locke, Jean-Jacques Rousseau, and Immanuel Kant).

Others thought that it’s only by the inevitable submission to a power higher than their own that people accept the least possible limits on their innate egoism, expressed in the simplest way as the essential instincts for survival and for the continuation of the species (for example, Sigmund Freud considered all culture to be founded on the obligatory “sublimation” of the libido), or as a will for absolute power, for the most extreme positions (like the one advanced by Friedrich Nietzsche).

Thomas Hobbes (1588–1679) declared also that “men in a state of nature, that is a state without civil government, are in a war of all against all.” This philosopher believed, however, that under these conditions, “life is hardly worth living.” “The way out of this desperate state is to make a social contract and establish the state to keep peace and order.” The need to preserve peace as a means to assure personal security is considered then as the “first law of nature.” The second one is to accept reciprocity in the limitation of personal liberty: “that a man be willing, when others are so too, as far forth as for peace and defence of himself he shall think it necessary, to lay down this right to all things; and be contented with so much liberty against other men as he would allow other men against himself.” Given the importance of the issue, Hobbes supports an extremely authoritative version of the “social contract.”

The utilitarian believes that a “rational egoism,” where everyone cares for his or her own interests and pleasure, although without causing any damage to others, is the only point on which members of a society need to agree to be able to have the best possible common life.

This kind of necessary “reciprocity” in the recognition of each person’s freedom and rights doesn’t

always imply a sense of true unity in a society. We may go even further, saying that not even equality among all members of a society could be founded on this elementary conception of “reciprocity.” Indeed, if there is common recognition of a certain hierarchy in the distribution of rights or power within a state (every social class recognizing the other classes’ position), reciprocity might very well contribute to the creation and the maintenance of a society of inequalities. Revolutionary movements are based on a “withdrawal” of reciprocity for the acceptance of the status quo, at a certain historical moment, arising usually from the parts of the society who don’t enjoy the same privileges as the others.

Reciprocity is, as we see, particularly linked to the idea of “justice.” John Rawls (1921–2002) tried to moderate the negative impressions given by the utilitarian individualistic view by establishing his concept of “justice as fairness” as a basis for the reciprocally accepted “social contract”: “a society satisfying the principles of justice as fairness comes as close as a society can to being a voluntary scheme, for it meets the principles which free and equal persons would assent to under circumstances that are fair. In this sense, its members are autonomous and the obligations they recognize self-imposed.” The persons participating in this hypothetical “initial” establishment of what is just in a society are considered here as “rational and mutually disinterested.” This means that “they are conceived as not taking an interest in one another’s interests,” but Rawls thinks that the pursuit of each one’s welfare separately will finally result in the fairest and most profitable common life for all.

There have been various reactions to this and other similar positions, on which a “liberal” conception of the best social organization is founded. Let us note here only two major ones.

The “communitarian” theories—of which one of the most well-known representatives is Charles Taylor (1931–)—accentuate the importance of the interrelation with others within a particular community for the realization of the best life for the individual. For these thinkers, the individual is essentially constituted through the sense of unity with others. There is no universal “natural” conception of ethical values, the stabilizers of a society, nor any abstract notion of justice, which might guarantee a successful political structure; only the empirical aspects of “socialization” can play this role. Communitarians particularly insist

on the importance of the reciprocal recognition of the “right to be different,” concerning especially cultural minorities.

The “ethics of discussion,” introduced by Jürgen Habermas (1929–) and Karl-Otto Apel (1924–), valorize more than any other theory the notion of reciprocity. “Communicational rationality” defines the ethical foundations of human societies according to these philosophers. As language is the means for the actions’ coordination, social life is essentially constructed on “reciprocal recognition,” that is, on the intersubjectivity of interlocutors who recognize reciprocally their rational competences of communication.

The sense given to reciprocity as the crucial factor of social equilibrium (we might indeed call it the “cement” of a society) doesn’t imply any other community than the one accorded by the human rational faculties, and the only necessary background for any agreement of social import is the possibility of arriving at common definitions.

It is perhaps an ingenious way to respect the liberty of thought and the equality of all, as well as to leave the door open for various definitions of reciprocity at the sociopolitical level as a result of discussion among the members of each society.

REDFIELD, ROBERT (1897–1958)

Robert Redfield, prominent anthropologist and Dean of the Social Sciences at the University of Chicago from 1934 to 1936, applied a functionalist anthropological

perspective to his comparative studies of Mexican communities at different stages of modernization.

Born in Chicago, Illinois on December 4, 1897, Redfield was the son of a prominent corporate lawyer, and his mother was the daughter of the Danish consul in Chicago. Redfield received his bachelor’s degree (1920), law degree (1921), and doctoral degree in anthropology (1928). Following his marriage to Margaret Lucy Park (1920), he visited Mexico where he became interested in ethnology. Upon his return to Chicago, Redfield was encouraged by his father-in-law, Robert Park of the Chicago School of Sociology, to study anthropology. The Chicago School was composed of distinguished sociologists who developed a social psychological perspective to view social change and social life. Among them, William I. Thomas, John Dewey, and George Herbert Mead dramatically influenced Park and the study of urban society and social change. In 1927, Redfield began teaching at the University of Chicago, and later became professor and dean (1934). He became a close friend of the university president, Robert Maynard Hutchins, and organized the Atomic Energy Control Conference (September, 1945) designed to help America adapt to the consequences of atomic weaponry through “world government.” In 1953, he became the Robert Maynard Hutchins distinguished service professor.

Redfield became interested in the modernization of small scale or primitive societies, focusing on communities in Mexico during his field research projects of the 1940s and 1950s. His comparative studies of four Yucatan communities were published as *Tepoztlan: A Mexican Village* (1930), *Chan Kom: A Maya Village* (1934), *The Folk Culture of Yucatan* (1941), and *A Village That Chose Progress* (1950). He became the most influential anthropologist to focus on the process of social and cultural change in the development of folk-to-urban societies and, together with the University of Chicago sociologists (the Chicago School), had an immeasurable influence on anthropology and sociology, especially social anthropology and the process of acculturation.

Influenced by the work of Milton Singer, he later expanded the focus of his studies to include cultural change as an historical study of civilization in *The Primitive World and Its Transformation* (1953), *The Little Community* (1955), and *Peasant Society and Culture* (1956). These works reflected his multidisciplinary approach to anthropological inquiry,

emphasizing a diversity of anthropological method and a universal perspective to examine human culture.

In 1930, Redfield was appointed a research associate at the Carnegie Institute of Washington. During his tenure he conducted field research in Yucatan and Guatemala while developing a historical paradigm of folk society and urban society including relative size, isolation, and homogeneity. He applied the paradigm in a controlled comparative study of the four Mexican communities—Merida, the capital city; a provincial railroad town; a peasant village; and a tribal forest community.

Redfield's works, especially *The Primitive World and its Transformation*, are required reading in social anthropology. Influenced by the social change theories of sociologists Ferdinand Tönnies and Émile Durkheim, his theory of cultural transformation from folk to urban ("civilized") society with resultant secularization, individualization, cultural disorganization, and anomie was widely accepted by sociologists and later social anthropologists. In the 1950s, he articulated his theory to other anthropologists via a series of lectures at universities in China, Europe, India, Puerto Rico, and the United States, later published in articles in the two-volume *Papers* (1962–63), which was edited by his daughter, Margaret P. Redfield. The articles capture his evolutionary conception of cultural history with progressions of heterogeneity and differentiation in social life as well as his universal perspective of anthropology and the humanities to research the reality of human experience.

Above all, Redfield was a humanist committed to freedom of thought and expression who inspired a generation of anthropologists and sociologists. His theory of cultural transformation, a historical timeline of dynamic social change in sociocultural evolution—from undifferentiated small-scale society featuring rural-agricultural social life with hegemony and cohesiveness to differentiated large-scale society featuring urban-industrial social life with heterogeneity and individuation—is a major contribution to the theory of social change embraced by scholars of today. His typological analyses of orthogenetic cities, wherein a moral normative order of folk culture pervades institutionalized social life in religion and customs, and heterogenetic cities, wherein folk culture disintegrates resulting in social disorganization of the old social patterns and development of new ideas and institutions, supported sociocultural

evolutionary theory of progression in technology, the division of labor and social roles, institutionalized patterns of social action, and self conceptions. Redfield advocated this theory in the classic tradition of social change, a synergy of theories developed by the European sociologists Tönnies and Durkheim and the Chicago School sociologists Thomas and Mead. The theory helped influence the early works of social anthropology and urban anthropology and sociology.

REICHARD, GLADYS (1893–1955)

Gladys Reichard was born in Bangor, Pennsylvania on July 17, 1893. Her family was of Pennsylvania Dutch heritage and she was raised in a Quaker household. After graduating from high school, she taught in the public schools for six years. In 1915 she enrolled in Swarthmore College where, in 1919, she received her AB in classics. She received a fellowship for graduate study and entered Columbia University in the fall of 1919. There she joined a large group of women who worked with Franz Boas. She received an MA in 1920 and began assisting Boas in his classes at Barnard College in the 1920–1921 academic year. In 1925, after receiving her PhD in anthropology, she began teaching full-time at Barnard College, where she remained on the faculty until her death in 1955.

She is widely considered an exceptional linguist and an extraordinary ethnologist. While her main scholarly focus was on Navajo people and culture, she

also studied Coeur d'Alene grammar and Melanesian design. Early in her career, she won a New York Academy of Sciences Prize for her monograph *Melanesian Design* (1932). But it was her work with the Navajo that would give her recognition as the most important female anthropologist to have studied with the Navajo, the largest Native American population in the United States.

She experimented with new forms of ethnographic writing, producing three descriptive accounts of Navajo weaving, family life, and ritual. The first, *Spider Woman* (1934), is a narrative ethnography centering on the trials of learning to weave, interspersed with descriptions of sheep dipping and a healing ceremony. The second, *Navajo Shepherd and Weaver* (1936), is a more technical monograph about Navajo weaving, while her third book, *Dezba: Woman of the Desert* (1939), is a novelistic account of Navajo life centering on the female head of an extended family. In this work she reveals that for the Navajo, there is an intimate connection between religious belief and physical health.

Beginning in the mid 1930s and continuing throughout the 1940s into the 1950s, she focused on the study of Navajo language and religion. She lived in the home of a Navajo curer and, together with the artist Franc Newcomb, published *Sandpaintings of the Navajo Shooting Chant* (1937), which includes a translation of the Shooting Way myth and a symbolic analysis of the sandpaintings. These paintings were reproduced in both line art and color in the book. Two years later, she published a sequel, *Navajo Medicine Man: Sandpaintings and Legends of Miguelito* (1939), in which she included a fuller discussion of the relationship between these paintings and the myth.

By the 1940s, she undertook a broader analysis of Navajo language, belief system, and religious practice. In her monograph *Prayer: The Compulsive Word* (1944), she outlined the content and structure of Navajo prayers. But her most important work, *Navaho Religion* (1950), is a two-volume study. In the first volume, she discusses Navajo ritual and symbolism, while the second contains a concordance of Navajo supernaturals, ritualistic ideas, and rites.

RELIGION

religion (Fr. *religion*, It. *religione*, Ger. *Religion*)

Hardly any term of the intellectual life seems to have such multifarious meanings as *religion*. Religion is of great importance for the development of mankind and its history, as it represents the human reaction to an extrahuman holy, transcendent, and divine object. The term religion has its etymologic and historical roots in the Roman world, unlike the term *faith*, which has its origin in the New Testament Paulinic word *pistis* (Greek), or *fides* (Latin). The Latin noun *religio* originates from the verb *re-legere*, which has the various meanings *to do sth. diligently*, *to do sth. again*, *to re-read sth.*, as M. T. Cicero has also uttered. The prefix *re-* could even be translated as *to do sth. diligently again and again*. That includes the careful execution of cults prescribed by law cults, which were valid only with exact observance of all these prescriptions. The Latin term *religio*, therefore, expresses in classical Roman culture the meticulous observance of cults and the consequent respect of man for their gods. Friedrich Heiler correctly puts the verb *re-legere* opposite to the verb *neg-legere* (to neglect). The derivation of the noun *religio* from *religare* (to connect, to reconnect) is in general to deny as one can see in it a feeling of an inner attachment to something transcendent, which was strange to classical beliefs. *Religio* in its character is in Roman antiquity more a virtue than a state of feeling. The diligent performance of rites was connected with a kind of *pious awe* that did not necessarily assume that the person who did the religious acts was inwardly moved:

Even after a precise analysis we will not be able to understand the feelings of a Roman when saying the word *religio*: the peculiar connection of awe and

diligence towards the gods that did not request an inner attachment. It is impossible for us to feel and comprehend this Roman *religio* and it will consequently always be strange to us. (Feil, 1986)

Just this matter makes the Roman *religio* incomprehensible for us, the adjective *religiosus*, which, according to Friedrich Heiler “initially marked a place or day as sacred,” is now applied to characterize people and means “pious” and having “fear of God.”

In another, later development, *homo religiosus* means “member of an order,” a person who lives according to the “evangelical vows” (poverty, chastity, obedience), and wants to be a good example to others in his religious life. From this meaning, maybe especially from the word *pious*, the noun *religion*, which may not be equated with the Latin noun *religio*, came into the Christian-shaped, Western culture.

The definition of religion as “devoutness or expression of devoutness” shows only inaccurately the full meaning of the word. The *fides quaerens intellectum* (“faith that searches for insight”) is also included in the concept of religion. In Christian antiquity, with St. Augustine, and in the Middle Ages, with St. Thomas Aquinas, *religio* means Christianity, the Christian religion alone. Non-Christian religions could only be called *lex*, *secta*, or *fides*. The term *lex* has a universal meaning, according to our expression “denomination or total structure of life.” There is also a *lex Christianorum*, which means “doctrine and law of the Christian religion.” The development of the term religion is by no means steady or logical. With the help of historical development, beginning with classical antiquity up to the *Augsburger Religionsfrieden* in 1555, which is characterized by the motto *cuius regio, eius religio* (“whose region, whose religion”), Ernst Feil was not able to find a continuous development to the modern term religion. *Religio* cannot be translated by or equated with religion in today’s meaning.

Leaving aside the Christian context of the word religion, one can define it as a relationship of man to a personal or

impersonal transcendent, in whatever shape (be it a divine *persona* or *impersona*) of *the Real*. In other European and non-European languages, the meaning of the Western-Christian term religion changes from *sth.*, which is owed to the transcendence to *law/doctrine* and *eternal, never-ending structure*. Apart from the more subjective *faith*, the term religion has a more objective meaning, similar to the distinction between *belief* (personal belief, conviction) and *faith* (universal faith, religion).

After this short etymological and historical study, we will now go on to describing the paradigmatical development of the modern term religion. According to Rudolf Otto (1925), a religion that believes in a deity of imaginable terms, is “rational.” He goes

Source: © iStockphoto/Simon Droscher.

further on the objectivity of a religion but in the same context emphasizes the “contrast between Rationalism and profounder religion.” Gustav Mensching also sees *the Sacred* as united with religion. He calls “religion” an “experienceable encounter of man with the Sacred” and an “answering act of man who is lead by the Sacred.” With the rationality of terms only, one cannot do justice to the term religion. Typical traits of religion are, according to Otto, the *tremendum*, the “awefulness,” that shakes man in awe of God, the mysterious, completely different being. But one has to differentiate this form of fear from the “natural, ordinary fear” of man, the “general world-fear.” The *tremendum* derives from a “numinous dread,” that at the same time terrifies and fascinates man. Religion thus is simultaneously the *fascinans*:

The qualitative *content* of the numinous experience, to which “the mysterious” stands as a *form*, is in one of its aspects the element of daunting “awefulness” and “majesty,” which has already been dealt with in detail; but it is clear that it has at the same time another aspect, in which it shows itself as something uniquely attractive and *fascinating*. (Otto, 1925)

At the beginning of his book *The Sacred and the Profane* (1957), in which he focuses on the nature of religion, Mircea Eliade deals with Rudolf Otto’s reflections. Eliade describes in his book the manifestations of religion and *the religious* in view of a world that dissociates itself more and more from religious dimensions. But even in a secular world, there is something sacred that is characterized as the opposite of the profane. It is always the same mysterious process: the *completely different*, a reality that is not of our world, manifests itself in things that are components of our natural, profane world.

The religious man Eliade speaks of several times, *Homo religious*, wants to live as long as possible in the sacred universe. The word *sacred* describes the dimension of the religious. This dimension surrounds and in some ways carries and holds the religious man. The secular man, who can live without any religious feeling, has a completely different experience, a secular experience of his environment. He lives in a desacralized world. The religious feeling has to find its way in another, maybe hidden, way. So he, the secular man, is differentiated from the *Homo religious*.

A good century and a half before Eliade, Friedrich E. D. Schleiermacher spoke of religion as a “feeling,” and before him, Jean-Jacques Rousseau did so. In his speeches *On Religion* (1799), Schleiermacher spoke of religion as a “feeling of infinity” and in *The Christian Faith* (1821/1822) in Section 4 as *Gefühl schlechthiniger Abhängigkeit* (“feeling of quintessential dependence”). *Quintessentially dependent* means here “to be conscious of a relation to God.” *Quintessential* means “absolute,” to “be free of all things.” According to Schleiermacher, everyone is shaped by two basic feelings: the feeling of dependence, which makes us the way we are through someone/something else, and the feeling of freedom, which makes something/someone else the way it/he is. The feeling of the *quintessential dependence* is related to the being of man in a specific way through the transcendent and is related to the fact that man is held and carried by the transcendent.

A quintessential feeling of freedom or a quintessential freedom cannot exist, for the transcendent in its nature cannot be created as a matter of our self-acting, which would be the condition for a quintessential feeling of freedom. This definition of the feeling of freedom shows in itself that we can only be dependent. The reason for this is that we can only shape these things with our human feelings of freedom, which are in their nature not transcendent. The transcendent does thus not come from human creativity. The transcendent is more the origin of the things that we can shape. Schleiermacher calls this transcendent “God,” outlined by the feeling of quintessential dependence.

If a man feels this quintessential, absolute dependence, then he also feels the relationship to God. In God only can one have the feeling of freedom, because He gives humans the possibility to create things the way they are through human will. Only in quintessential, absolute dependence in the relationship with God, does man get his feeling of freedom. So the basic stage of man, which is shaped through the quintessential dependence and the feeling of freedom, is made possible. In Goethe’s *Faust* (1808), religion is characterized as a feeling, too. Faust’s answer to the *Gretchen-Frage* is: “Call it, as you like: Call it luck! Heart! Love! God! I do not have a name for it. Feeling is everything; the names mean nothing.”

Immanuel Kant’s work is in strong contrast to the definition of religion as feeling: There is no way that

one could conclude the certain feature of direct divine influence by a feeling, as is shown by Kant's work *Die Religion innerhalb der Grenzen der bloßen Vernunft* (*Religion Within the Limits of Mere Reason*) (1793). Furthermore, religion must be based on reason alone in order to be universal. The religion has to be a *reine Vernunftreligion* (pure religion of reason). However opposing these two definitions of religion may be, the "feeling," as Schleiermacher calls it, and Kant's "pure religion of reason" coincide, though, in the fact that religion is something inward. In this way, at about 1800, a concept of internal religion developed, which proved to be effective up to the 20th century. This is portrayed especially by the statements on religion by Ernst Troeltsch, in 1895: Religion "is fluent and vivid at any time, depending on the direct touch of God, it is internal, personal, individually and abruptly in the highest degree."

Source: © FreeStockPhotos.com.

We can regard Paul Tillich's works as examples of the effective power of the concept of religion. He goes away from feeling as a determination of religion, in a different way than Immanuel Kant, as religion stays in this connection to the pure subjectivity of emotion; and thus declines, as religion loses its seriousness, its truth and its highest sense, and stays empty without a highest content. In his essay *Religion als eine Funktion des menschlichen Geistes?* (*Religion as a Function of the Human Mind?*) (1955/1956), Tillich defines religion as "something that concerns us immediately," in the deepest sense of the word. *What concerns us immediately* becomes tangible in all creative functions of the human mind. But this does not mean that religion is a fiction of the human mind that is created by man himself.

Similar to Schleiermacher, Tillich claims that man's mind was able to be creative in relation to himself and his world, but he could not be that in his relationship to God. It is more likely that it is meant that religion contains all areas of the life of the human mind, as it is the substance, the basis, and the depth of the human intellectual life. In this, however, religion is not based in any kind of function of the mind; it is universal. Religion is consequently *das Unbedingte* (the unconditioned component) in every situation.

At a different part, Tillich characterizes religion in 1928/1929 as follows:

In every religious conscience, the first and basic thing that carries everything, is a conscious of the unconditioned, the inevitability of what is given in the religious reality, an awareness of what concerns me concretely and absolutely, the decision between life and death in a way which goes beyond the physical being or not being. . . . If every man, if all parts of our lives are concerned by what is meant with the concept of religion, this concept grows to be universal in its being unconditioned. It grows to something that fits for all parts of reality and for everyone in reality. (Tillich, 1964)

According to Tillich, being moved by religion is always related to a *religious object*: "It may be expressed as the inexpressible but it is expressed; and in being expressed, it includes a community, to hear, to perceive and to transmit." In this statement, Tillich expresses two things: On one hand, he wants to show that religion is always related to a content that is inexpressible in the end, and on the other hand, he portrays the social dimension of religion. The objectivity of religion is acquired by this social dimension;

nobody is on his own in feeling any kind of religious emotion, in being religiously moved. According to Tillich, religion is consequently situated in the human, who is touched by a *offenbarten Unbedingtheit* (revealed unconditioned being). This can generally be applied to everyone. The feeling of being touched is always related to a religious object. In the *religious reality*, however, things are always mentioned that go along with a secret consciousness: "*tua res agitur* [Horaz, *Epistulae*. I, 18, v. 84]: You, your issues, are concerned!"

Two definitions of the concept of religion Tillich gives differ crucially from the traditional one: First he speaks of the *autonomous religion*, which does not know a representational God and consequently no

form of prayer either. Despite this, religion is not ungodly or impious. It just knows no kind of ecclesiastical objectification of God. With mysticism, it is different again; mysticism elevates itself beyond the objectification of God. Second, in his essay *Christianity and the Encounter of the World Religions* (1961/1963), he mentions "quasi-religions" that are similar to a religion and have some features in common with a religion, but they are only related to secular things and are consequently secular institutions. Tillich speaks of fascism and communism as "most extreme examples of quasi-religions today" because "they are radicalizations and transformations of nationalism and socialism, respectively, both of which have a potential, though not always an actual religious character." Tillich here differentiates between *quasi-religions* and *pseudo-religions* that pretend intentionally to be similar to religion. Due to Tillich's considerations, especially, the expansion that the concept of religion underwent since the beginning of the 19th century becomes clear.

Quasi-religions and pseudo-religions must be strictly distinguished from the traditional religion, by others (such as Eric Voegelin and Raymond Aron), seen as a *political religion* in another concept. So, an explosive nature is exhibited in the relationship between religion and politics, as it is expressed in the concept of political religion, and furthermore in the concepts

of *state religion* or *civil religion*. The roots of the term political religion as *religio politica* go back to the early 17th century. Since the 1930s, it served to classify the political totalitarian mass movements of this time in a critical attitude toward ideology. But this modern political religion must be clearly distinguished from the political religion in classical antiquity and the later concepts of state religion and civil religion that tried to institutionalize the relationship between religion and politics.

All in all, it is possible to denote religion as something that is situated in man and must be defined as a relationship and interchange between man and a transcendent reality that is relevant for him. The regard to transcendence, however, is not only for religion a

decisive criterion. Religions are, rather, connected by a kind of *Familienähnlichkeit* (family resemblance), as defined by Ludwig Wittgenstein, and thus partly determine each other. They demonstrate similarities that connect them. But these similarities must not necessarily be alike in all religions. Regarding those similarities, the reference to transcendence plays an important role, as well. According to John Hick, another fundamental family resemblance, in addition to the reference to transcendence, is the soteriological content of religion, which describes the ability of a religion to redeem and give salvation. This quality is a feature that all religions have in common in various manners, however different their contents and traditions may be. Hick states that the validity of religious traditions is also measured accordingly.

The modern concept of religion is carefully defined as *generic term* by Ernst Feil, as a marking that slowly has grown in importance in modern age and in no way portrays the original meaning of the word religion, as its meaning does first describe all imaginations, attitudes, and actions concerning this reality, which humans accept as and call powers or power, spirits or demons, deities or God, the Sacred or the Absolute, or just transcendence. In the end of the first part of his study, however, Feil makes clear that *religio/religion* was not used as a collective name for each belief and as a generic term, in which various beliefs are summed up. From antiquity up to the *Augsburger Religionsfrieden* in 1555, the term *religio* was only used in a very narrow sense: in the beginning with reference to the exercising of the cult prescribed by law, and later with regard to the Christian denomination. It was long after this that *religio/religion* underwent an extension of its meaning that led to the modern understanding of religion.

Religion is more than the mere name of a belief; it expresses that man is concerned about something that is beyond him. Summing up, one could characterize religion as follows: First, there is no generic term for all religions of mankind. Second, there is no term that can include all aspects of what is nowadays meant by “religion”; even all these terms together cannot cover everything. Third, in contrast to the modern meaning of religion, earlier terms put the emphasis on the external practice of religion, on the observance of ritual instructions and regulations, and obedience to religious law. These terms, however, are neither unambiguously classified nor do they appear in an outstanding function. It is this final characterization

that portrays the broad conceptual frame of the modern concept of religion.

In the late 19th century, anthropology emerged as an academic discipline against a background of intellectual foment and rapid advances in the sciences. During this formative time, religion was the subject of many travelogues, popular books, and scholarly studies. Nineteenth-century European colonial expansion, and the scholarship it engendered, exposed the Western world to a large number of different religious belief systems, which challenged many Western assumptions about religion, and which would

Source: © iStockphoto/Martin de Wit.

eventually contribute to significant changes in Western Christianity. New approaches to Biblical studies, such as Higher Criticism, embraced this new scientific and cultural knowledge, but there were religious reactions against the social and intellectual changes taking place as a result of this new knowledge. The Holiness/Pentecostal movement and the rise of fundamentalist Christianity in the late 19th and early 20th centuries were types of revitalization movements that developed strong anti-intellectual traditions that resisted the objective, scholarly study of religion, the theory of evolution, and the materialistic naturalism of the scientific worldview.

A number of 19th-century scholarly studies about religion were concerned with understanding the origin of religion and concerned with the development of religious practices, which paralleled a similar concern in the biological sciences with the origin of life and with evolutionary change. Later, more anthropological studies would lose interest in the question of origins and become more concerned with social aspects of religion, or with the symbolic nature of religious systems.

In the mid-19th century, F. Max Müller, who studied Indian religions, proposed that religion began when people personified the forces of nature. From his perspective, such personifications were a mistake, or “disease,” of language, which meant that religion was little more than a cognitive mistake or delusion. He called this view *naturism*. All human beings have had to deal with forces of nature that terrified them, such as tornadoes, hurricanes, earthquakes, floods, and so on, and all human beings in primitive societies have been subject to the same mistakes of language. So, naturism provided an explanation for the universal presence of religion in all human societies.

Edward Tylor, in *Primitive Culture*, suggested that it was a belief in spirits that led to the origin of religion. Death is a universal human experience, and, according to Tylor, the belief in spirits began when people, faced with explaining the difference between “living” and “dead,” hypothesized the existence of a “spirit” that was present in life and absent in death. He called this idea *animism*. Once human spirits were hypothesized, it was only a short intuitive leap to hypothesize other spiritual beings. For Tylor, elaboration on the belief in spirits explains the origin of religion.

Another scholar, R. R. Marett, in *The Threshold of Religion*, proposed that a belief in a powerful impersonal force, which pervaded the entire universe, preceded animism, and was, therefore, the beginning of the development of religion. He called this belief in a powerful, impersonal force, *animatism*.

Émile Durkheim offered a more sociological perspective on the origin of religion in *The Elementary Forms of the Religious Life*. He saw religion as a collective behavior that began when people categorized themselves after the patterns of nature, and then abstracted those categories into symbols, and, finally, worshipped those symbols with specific rites. Essentially, a society worshipped an abstraction of itself. He believed this system to be the earliest form of religion and called it *totemism*.

Cultural anthropology eventually moved away from trying to explain the origin of religion in human societies but has retained the concepts of naturism, animism, animatism, and totemism to describe various aspects of religious belief systems. The underlying assumption of those four concepts, however, that disturbed religious people in the Western world during the late 19th century was that the supernatural did not exist and that only the natural world was real. Many religious leaders and scholars during that time

saw the rise of materialistic naturalism in the sciences, humanities, and in popular thinking as an assault on faith, and as an attack on the institutional legitimacy of religion.

Cultural anthropologists have since developed a number of explanations of religion that have avoided the question of origins, but all have retained some form of materialistic naturalism as a foundational assumption. Marxist explanations depicted religion and religious belief as fictions that supported the *status quo* and that maintained class differences. Functionalists, like Bronislaw Malinowski, A. R. Radcliffe-Brown, and E. E. Evans-Pritchard, explained religion as providing explanations that satisfied human needs or maintained social structure. Cultural material explanations, like those of Marvin Harris and Roy A. Rappaport, saw religion as doctrine and ritual that supported cultural adaptations to the environment and acted as feedback mechanisms to keep complex ecological systems stable over time. Finally, symbolic anthropologists, such as Clifford Geertz, viewed religion as a system of symbols that ascribe meaning to the universe and to existence.

Because of the naturalistic assumption of these theories, the intellectual divide between anthropologists who study religion and religionists who study religion is at least as great today as it has ever been. This situation presents many epistemological and practical problems for the ethnographer doing research.

Anthropologists doing fieldwork frequently encounter explanations and views that differ markedly from the materialist explanations and views characteristic of a Western scientific perspective. This creates a representational dilemma for the researcher. Robert Shanafelt points out that we cannot simply ignore the truth value of what our informants tell us, as if it did not concern us, because whether or not our informants are correct determines whether or not our explanations of their beliefs and behaviors make sense. Consequently, he says that it should be an anthropological concern whether or not the supernatural exists. So, while anthropologists may accurately depict their informant's claims and experiences concerning the supernatural as true within the informant's own religious system, that depiction is simultaneously, either implicitly or explicitly, painted as false by the naturalistic assumptions in anthropology. Thus, the anthropologist's work becomes a negative judgment of the informant's worldview. Also, invoking cultural relativism in our approach does little to

help; either we suspend our value judgments, or we do not. We cannot have it both ways.

There is no easy resolution to this difficulty. Clearly, the naturalistic assumption in anthropology and in the sciences is supported by an incredible amount of empirical data. Equally clear is the fact that many religious people reject that assumption in favor of some supernatural explanation. So, how does the anthropologist respect and value perspectives that he or she believes to be false?

On December 4, 1998, at the 97th meeting of the American Anthropological Association in Philadelphia, there was a session titled, "The Spirit Hypothesis: Scientific and Participant Validation." Papers were presented by Antonia C. Mills, David J. Hufford, Michael J. Harner, and Yves Marton, who was the session organizer. Helmut Wautischer chaired the session, and Edith Turner was the discussant. Mills' paper argued that anthropology, and other disciplines, knew too little about "soul-stuff . . . to discount nonwestern conceptions as invalid." Hufford discussed the "spirit hypothesis" and why it was desirable to systematically investigate it in anthropology, regardless of whether or not the spirit hypothesis was true, false, or indeterminate. Harner pointed out that the spirit hypothesis was not falsifiable, in the Popperian sense, and that the scientific view—that spirits do not exist—was also not a falsifiable position. Harner also argued that spirit encounters are empirical facts to shamans, based on their own experiences, and not just matters of faith. Finally, Marton explored how religious leaders and spiritual leaders, compared to anthropologists, differently interpret evidence.

That session was so well attended that every square foot of floor space had someone occupying it. After the chairs filled up, people sat on the floor and overflowed into the hallway, and so many questions followed the discussion that the session ran over its allotted time.

A number of questions and discussion also concerned "people of faith" in anthropology. The importance of this session is that it has generated much subsequent discussion and research. This session highlighted what remains an important problem in anthropology.

In spite of the materialistic and naturalistic assumption that divides anthropology and religion, some aspects of anthropological research have proven useful in religious studies. Anthropological archaeology, linguistic anthropology, and cultural anthropology have all made contributions to studies of the

world's sacred texts. Likewise, cultural and linguistic studies have produced many missionaries that are more sensitive to the cultural differences of the people they proselytize. Also, courses whose content is largely anthropological can be found in religion departments at a lot of faith-based colleges and universities. Such courses are offered to a number of different majors: intercultural studies, missiology, pastoral ministry, theology, and Bible majors, to name a few. Apparently, in many areas not directly associated with the supernatural, there is plenty of room for anthropology to inform religious studies.

The study of religion will continue to be important to anthropology, and, no doubt, the results will also continue to be of interest to religious and spiritual leaders, whether or not they accept the anthropological view.

RELIGION AND ENVIRONMENT

Spiritual ecology may be defined as a complex and diverse arena of religious, spiritual, intellectual, and practical activities at the interface of religions and spiritualities on the one hand, and on the other of

ecologies, environments, and environmentalisms. The term is applied as a parallel to other primary components of contemporary ecological anthropology like primate ecology, cultural ecology, historical ecology, and political ecology. The word spiritual is used, rather than religion, because it is more inclusive. While spirituality is part of religion, there are also individuals who pursue spiritual beliefs, values, and actions independently of any organization of adherents to a particular religion. Also, other labels for this subject, such as religion and environment, religion and ecology, religion and nature, ecotheology, and the like, are awkward and problematic in other ways. Moreover, the qualifier spiritual is used to be provocative; that is, to shake people out of their mental and social complacency for the simple reason that business as usual is a major obstacle to reducing, let alone resolving, the eco-crisis. Instead, it is increasingly recognized that a radical rethinking, re feeling, and revisioning of many human-environment relationships is imperative for the survival of humanity and the biosphere.

Since the first Earth Day on April 22, 1970, an increasing number of diverse individuals and organizations worldwide have recognized the gravity and urgency of the ongoing environmental crisis. Nevertheless, in spite of the development of numerous and varied environmental initiatives, the crisis has not subsided. Indeed, it has been getting far worse. For instance, there are many indicators that global warming is a reality. This is affirmed not only by an overwhelming consensus of the international community of scientific experts on global climatic and environmental changes, but even through personal experiences with weather and climate by the public in many parts of the world. Obviously the various secular initiatives, including the development of environmental aspects of the sciences, technology, education, philosophy, ethics, history, politics, government, law, economics, and the like, have not reduced, let alone resolved, the eco-crisis. Certainly they are necessary, but just as certainly they are not sufficient. The environmental crisis will only turn around for the better when a sufficient percentage of humanity thinks deeply enough and acts radically enough to profoundly change their detrimental impact on nature. Spiritual ecology may be the last hope for helping to trigger such a turnaround by humanity.

Since the 1990s, an accelerating number of diverse individuals and organizations have been seriously

exploring religion as a last resort for resolving the eco-crisis. However, this movement is not offered instead of previous secular approaches, but in addition to them as a complement, with the hope of finally turning things around for the better. No particular religion is designated as the sole solution. Instead, scientists, scholars, educators, clerics, adherents, politicians, and others are probing deeply into their own religion or spirituality for elements to construct more viable environmental worldviews, attitudes, values, and practices for themselves and others. Mary Evelyn Tucker optimistically refers to this worldwide movement as religions entering their ecological phase in a second axial age.

This arena of spiritual ecology has grown exponentially throughout the 1990s to this day. Perhaps the most outstanding illustration of this phenomenon is the Web site of the Forum on Religion and Ecology (FORE) in the Center for the Environment at Harvard University. This site surveys the major religions of the world, including indigenous traditions, in relation to ecology. It is in eight languages and receives as many as 60,000 visitors monthly. The site lists ten books, developed by the FORE, each on a different religion in relation to nature. There is a summary and table of contents for each book. The religions covered in these impressive volumes are Buddhism, Christianity, Confucianism, Daoism, Hinduism, Indigenous, Islam, Jainism, Judaism, and Shinto. These books are the most visible major result of ten international conferences held from 1996 to 1998 at Harvard University. In total, they involved more than 700 participants. The books each have substantial bibliographies, as does the FORE site. In addition, culminating conferences were held at the American Academy of Arts and Sciences, American Museum of Natural History, and the United Nations. The principal catalysts in the Harvard and FORE initiatives are Mary Evelyn Tucker and John Grim of Bucknell University.

A second major academic initiative is the two-volume *Encyclopedia of Religion and Environment*

Source: © FreeStockPhotos.com.

with Bron Taylor as Editor-in-Chief. It includes over 1,000 entries written by 518 authors. The project was developed from 1997 to 2005. Based at the University of Florida, Taylor is on the faculty for a special graduate concentration on religion and nature established in the Department of Religion in 2003. That same year a Spiritual Ecology Concentration was implemented in the Ecological Anthropology Program at the University of Hawai'i that operates at the undergraduate and graduate levels. These two unprecedented academic developments reflect the growth and maturation of the subject with the first textbook by David Kinsley in 1995 and the first major anthology edited by Roger S. Gottlieb in 1996. The following year the first academic journal devoted to the subject was launched, *Worldviews: Environment, Culture, and Religion*.

Spiritual ecology, however, is not merely an academic matter. Proponents are serious about the ultimate cause of the ongoing and worsening environmental crisis, which they view as a moral crisis. A multitude of various practical activities beyond academia are underway. For instance, in 1995 the Alliance for Religions and Conservation was established in association with the World Wide Fund for Nature in the United Kingdom. They have developed thousands of projects throughout the world linking sacred places with biodiversity conservation. Another practical example is the United Nations Environmental Program resource volume of over 800 pages, edited by anthropologist Darrell Posey and others in 1999.

Also impressive is the UNEP book edited by Libby Bassett and others in 2000. Secular nongovernmental environmental organizations that have become interested in spiritual ecology include the Worldwatch Institute in Washington, D.C., which published an assessment of the mutual relevance between religions and environmental conservation in 2002.

Spiritual ecology is a most exciting and promising new frontier for research as well as teaching in anthropology and beyond. Of course, there are pioneers from decades ago to the present, even if they wouldn't necessarily identify themselves as spiritual ecologists. They include anthropologists Kelly D. Alley, Eugene Anderson, Susan M. Darlington, Philippe Descola, Stephen J. Lansing, Kay Milton, Richard K. Nelson, Darrell Posey, Roy A. Rappaport, Gerardo Reichel-Dolmatoff, and Leslie E. Sponsel who have authored field-based case studies on the relationships between religion and environment.

In this arena, anthropologists can apply appropriate theories and methods encompassing their traditional framework of holism, culture, ethnographic fieldwork, and cross-cultural comparisons. In particular, there is a dire need to go beyond scholarly analyses of the relevance of points in sacred texts and other literature for spiritual ecology to what anthropologists themselves do best; namely, fieldwork in communities through participant observation, interviewing, surveys, and other methods and techniques. In other words, research on spiritual ecology needs to encompass context as well as text, and actions as well as ideals. Most of all, fieldwork is needed to systematically, empirically, and critically explore the environmental consequences of religious or spiritual behaviors in specific ecosystems. Sacred places in nature provide an especially useful focus conducive to such research.

Of course, as in anything, there are skeptics, critics, and opponents. Among these are individuals who ascribe to scientism, the myopic and reductionistic pursuit of science as if it were the exclusive route to knowledge, understanding, and truth about all of reality. Other opponents include extremists ascribing to rationalism, humanism, secularism, Marxism, materialism, nihilism, atheism, and agnosticism.

Certainly not everyone needs to join the spiritual ecology movement; there are many other valid and useful ways to pursue human ecology and environmentalism. Diversity is the key to adaptive success, and that principle applies to science and scholarship

as well. However, for many of those who combine intellectual curiosity with an open mind and who have a deep concern about the health of the planet that is our only home, spiritual ecology provides some hope for a better environmental future.

This is not to say that religion is an unmixed blessing by any means. Religion can be used by humans for better or worse, but for that matter, so can science, technology, medicine, education, government, politics, and law. For instance, modern science and technology can cure some horrible cancers, but they also provided the carcinogenic chemicals that permeate our air, soils, water, and food, as Rachel Carson warned in her classic book *Silent Spring* more than four decades ago.

One of the most striking positive attributes of spiritual ecology is that it has proven to be a very special arena in which individuals and organizations from quite diverse religious persuasions can actually find common ground to engage in constructive dialogue and collaborative initiatives, unlike most sociopolitical issues regarding life and death, such as abortion, capital punishment, euthanasia, terrorism, and war. Likewise, spiritual ecology is conducive to such cooperative initiatives between representatives from science and religion, this after several centuries of antagonism, and in contrast to the situation of recent controversies such as cloning, stem cell research, and other biotechnologies.

In terms of theory, one of the potential contributions of spiritual ecology is to challenge a number of binary oppositions that have persisted throughout Western intellectual history, including science/religion, rational/irrational, objectivity/subjectivity, fact/myth, nature/culture, natural/supernatural, and profane/sacred. The time is long overdue to transcend such simplistic, reductionistic, and dualistic thinking, albeit without denying the occasional validity and utility of some analytical contrasts.

In conclusion, spiritual ecology has already made a significant contribution in academia and beyond, and it still holds the promise of much greater achievements in coming decades. It complements secular approaches to dealing with the ecocrisis. As in the case of the secular approaches, spiritual ecology is not sufficient, but it is necessary. Moreover, perhaps it will finally help turn things around for a better future, one which is more sustainable, greener, just, and peaceful. Anthropology has a distinctive contribution to make in this enterprise, and spiritual ecology also

has a contribution to make to both teaching and research in anthropology.

— Leslie E. Sponsel

RELIGION, LIBERAL

Liberal religion is distinct from the liberal wings of particular religions such as liberal Catholics, liberal Baptists, liberal Hindus, and the like who seek a liberal way through their own particular religious traditions. Depending on the relative strength of the anti-liberal wing of those same religions, liberal wings of the various religions will come and go, wax and wane, or sometimes develop into completely new religions. Although there are certainly expressions of the liberal religion phenomenon in religion, liberal wings of religions are not the liberal religion phenomenon itself.

Anyone or any religion or any society can manifest principles of liberal religion. These principles are expressed within a particular religion as one among its many manifestations. Or they are expressed outside religion, moving beyond institutionalized religion if liberal religious impulses have been too thoroughly repressed.

The religious truths of liberal religion are, by necessity, open to questioning. Perhaps surprisingly, this does not mean that liberal religion necessarily rejects the possibility that its truth claims are in fact

eternal. It merely means that this eternality will remain a possibility, a speculation. The beliefs of liberal religion may be strongly held, but liberal religion welcomes further development, interpretation, and even rejection when proven by experience or new revelation to be inadequate or just plain wrong. Any investigation into liberal religion should beware of claims that practitioners “have no beliefs,” “can believe anything they want,” or “are non-creedal.” Even “non-creedalism” is itself a belief and should be understood as such. That the many creeds of liberal religion are acknowledged as contingent on the process and progress of truth does not thereby render those creeds nonexistent. Liberal religion simply refuses to confer on creed the status of dogma.

Perhaps the most fundamental doctrinal aspect of liberal religion is the ultimate freedom of the individual to question all aspects of religion, even the aspect of questioning itself. This has, at times, earned the religious institutions that fully embrace the liberal religion phenomenon the name “Free Religion” or “Free Thinkers.” But this liberal religious tendency is, of course, manifest in a wide range of religious institutions. This fundamental aspect of liberal religion asserts itself whenever forces within religious organizations bring traditional or historical beliefs or practices into question. Contributing to the constant reformation of religion through liberal religion, the most basic assumptions, even those understood as eternally true (for example, God’s grace, the finite power of human sin) are open to interrogation and, if need be, reform. Because of this incessant questioning, liberal religion presumes neither inevitable progress (a common hope of liberal religions) nor inevitable degeneration (a common lament of the illiberal).

Liberal religion, liberal religious movements, and individual liberal religionists seek to discover the good, the true, the beautiful, and the loving for their time and place, reforming or rejecting those religions, or those individual aspects of particular religions, that do not fit the best definitions and highest aspirations. This constant pursuit acts as barometer or compass for reforming religious institutions, revealing the excesses and deficiencies to which even avatars and scriptures are susceptible. Revelation from avatars and scriptures are not by necessity rejected, but liberal religion claims that revelation is never final.

Liberal religion encourages the use of reason and emotion, science and intuition; it often does not offer

answers per se, but rather offers guidance for how to deal with situations as they arise. It is through the attempts at getting closer and closer to the divine life and the highest form of human life that liberal religion provides a way of discerning the best religious life.

Seeking to discern genuine religion, liberal religion freely investigates wisdom and understanding from every religious impulse of humankind. Through investigating and sometimes integrating aspects of exogenous religious systems, liberal religion balances insights from the various, different, similar, and sometimes stubbornly contradictory religions in the world. Liberal religion welcomes insights from poetry, art, literature, human experience, scientific discovery, and the like. Similarly, liberal religion promotes the understanding of humanity as part of the natural world. Nature is considered a source of life's ongoing revelation of itself. Through philosophical and scientific reflection, as well as through immediate experience and appreciation, the realities and lessons of nature are considered to be immanent and accessible epiphanies. Thus, liberal religion sees progress in natural sciences as progress in religious understanding.

This brings us to another liberal religion doctrinal tendency: toward belief in the accessibility of religious truth to all irrespective of their religion, social status, education, and so on. Profound religious truths are discernible without necessarily the benefit of specific religious authority such as priest, prophet, scripture, ritual, congregation, or other social construction. Liberal religion observes that all religious faith is, however, *necessarily* filtered through the authority of the individual faithful. Liberals within religious traditions know that they are the ultimate authority by which they accept the authority of their religious tradition. This does not exclude the possibility that one's particular religion might be preferred, only that this preference requires an accompanying humility based on the knowledge that religion is, on some level, autobiography.

Probably because of this humility when it comes to religious truth, liberal religion argues for broad tolerance when it comes to religious beliefs and practices of others. Tolerance of a wide diversity of religious views prevails where liberal religion doctrines prevail. Where liberal religious insights argue for intolerance, such as with the intolerance for the beliefs of Nazis or the Ku Klux Klan, they do so precisely because they believe they are serving greater tolerance.

Mysticism in religion, the socially conservative aspects of religion, and fundamentalism in religion have been and continue to be studied extensively. Liberalism in religion is less studied but no less important to understanding religion as a human phenomenon.

COMPARATIVE RELIGION

Cultural anthropologists recognize that studying the religious beliefs of a particular culture is integral to understanding the culture itself, and comparing religious beliefs across cultures provides a more comprehensive explanation of human behavior as a whole. Anthropologists know that while all societies profess a belief in some sort of religion, those religious beliefs may not be shared outside a particular society. While some anthropologists argue that anthropologists should attempt to determine the truth or falsity of religions that they study, most anthropologists are inclined toward seeking objectivity in their work. Studies of some religious beliefs, such as belief in the occult, may require scholars to suspend rationality in order to study religions from the perspective of believers.

Historically, anthropologists have studied magic within the context of understanding religion because it forms the foundation for religious beliefs in a number of cultures. Beginning in the late 20th century, however, an increased public interest in magic, responsive in part to the success

of British author J.K. Rowling's Harry Potter series about a young wizard, New Zealander Peter Jackson's adaptation of J.R.R. Tolkien's *Lord of the Rings* fantasy trilogy, and American television shows such as *Buffy*, *The Vampire Slayer* and *Angel*, alerted anthropologists to the need to examine beliefs in magic within the context of cultural studies of both modern and postcolonial states. Those who prefer to approach anthropology as a science have harshly criticized this new approach to the study of so-called anthropological exoticism.

Early anthropological interest in the study of the occult received a major boost in 1937 with the publication of Sir Edward Evans-Pritchard's *Witchcraft, Oracles, and Magic among the Azande*, which established a theoretical framework for the study of magic within the context of ethnography. Evans-Pritchard concluded that there were vast differences in witchcraft as practiced by the Azande in Africa and beliefs identified as witchcraft in Western societies. In an attempt to analyze witchcraft within the context of postcolonialism, Henrietta L. Moore and Todd Sanders have examined the interactions between the mores of contemporary Africa and the traditional views and practices of African witchcraft. Other contemporary African scholars such as Barry Hallen, J. Olubi Sodipo, A.K. Appiah, and V.Y. Mudimbe have also taken up the Evans-Pritchard banner, further refining the anthropological approach to the occult within the context of religious beliefs.

While most anthropological studies of magic have focused on African cultures, some contemporary scholars, such as Susan Greenwood, have examined witchcraft in Western cultures. In *Magic, Witchcraft, and the Otherworld*, Greenwood reports on her observation of witchcraft in contemporary England by focusing on comparisons of high magic, Wicca, and feminist witches. Like anthropologists Jeanne Favret-Saada, Paul Stoller, and E. Turner, who advocate experimental approaches to the study of witchcraft, Greenwood contends that the correct way to study alien belief systems is to suspend personal beliefs while participating in the rituals of the group under review.

— Elizabeth Purdy

RELIGIOUS RITUALS

A religious ritual is a prescribed, routinized, and ceremonial action or set of actions, the function of which is symbolic and has specific significance to the performer and the performer's community. On a very basic level, rituals are an inherent part of living. They can be seen in many forms of animal life, from ants to humans. The importance and power of ritual can be seen in the persistence of rituals in contemporary secular society. These range from greeting rituals to elaborate and highly complex governmental and national rituals. Religious rituals have additional deeply rooted meanings and functions, and they also serve as public or private displays of one's commitment to and faith in a system of beliefs. Many of the various types of rituals that can be found in cultures and traditions throughout the world share common themes, patterns, and purpose. Ultimately, however, rituals serve as vehicles to create or enhance the proximity of the rituals' beneficiaries to the realm of the divine, to influence the divine or supernatural, or to facilitate the attainment of power associated with the spirit being who is propitiated. In their enactment, rituals take individuals out of the ordinary realm of everyday mundane experience and create for them an opportunity to undergo something higher, more sublime, and closer to the divine. There are certain aspects and parts of ritual that can be found throughout the religious cultures of the world. The more common elements and themes are discussed below.

Purification and Sanctification

Because of the sacredness associated with most ritual performance, many are preceded by rituals of purification. These typically include physical cleansing of participants, ritual items, and ritual sites. Additionally, fasting, abstinence, solitude, and other similar practices may be performed. These are meant to help prepare the participants physically, emotionally, and spiritually to perform the subsequent rituals, as well as to receive the blessings, forgiveness, or powers that other rituals are meant to confer. Purification rituals may also be done on their own as a preparation for most everyday activities, from eating to working to sleeping.

Personal, Public, and Performer

When the individual who performs a ritual is a commoner or lay person, the ritual is generally a personal one. Rituals of ablution, prayer, meditation, offerings at a home altar, and so on are typically undertaken by lay persons as a part of the daily enactment of their religious beliefs. When the performer is a designated officiant, such as a priest or a shaman, then the ritual is a mediated one, undertaken for the benefit of another (usually a lay person). In such cases, the beneficiary of the ritual will likely pay the officiant, with money or goods, for the rituals performed. Most religious traditions have individuals who are specifically trained and officially authorized to perform such rituals. They are generally referred to in English as “priests,” and their primary function is to oversee both mediated and public rituals. The latter are meant to draw the community into joint participation and expression of acceptance of the beliefs and values being expressed by the ritual. They also function to promote a sense of unity, in which individuals are inspired to support and promote the communal system of behavior. Indigenous cultures often have shamans who perform rituals as well. In these cultures, shamans are called upon for special and individualized rituals, such as performing exorcisms, curing illnesses, warding off curses, and mediating with the world or spirits and ancestors.

Beneficiaries

Every ritual has a beneficiary, someone or something for which the ritual is undertaken. In a personal ritual, the beneficiary is generally the person who performs it. In a mediated ritual, on the other hand, the beneficiary is the individual for whom it is performed, or the inanimate objects for which or with which the ritual is enacted. An example of the latter is a ritual done to purify or sanctify a place or object. In the process, not only is the place or thing blessed, but the objects used in the ritual may then be seen as similarly sanctified. Typically, the rituals believed to be the most powerful are mediated ones, performed by qualified and authorized officiants.

Representational vs. Presentational

In explaining the role of symbols, Roger Schmidt provides the useful bifurcation of representational and presentational. The former has emblematic value, while the latter “presents” or shares in the essence of that which is symbolized. These categories are useful in application to ritual roles and functions as well. Secular rituals are, for the most part, representational in that they are not believed to cause any fundamental alteration of the participants. Their functions and significances are generally personal, social, symbolic, and not necessarily mandatory. Thus, attendance at one’s graduation ceremony, for example, is not a pre-

requisite to graduate. A particular type of greeting on meeting someone may be a traditional ritual but is not always required. Most religious rituals, on the other hand, are presentational. They are believed to have the potential to bring about a fundamental change in the rituals’ beneficiaries as per the particular ritual performed, and they are traditionally mandatory. A blessing of food actually alters the spiritual essence of the food. A marriage ceremony actually changes the participants spiritually, as well as legally and socially.

Not all religious rituals are presentational, however. A good example of the difference can be seen in the communion bread and wine preparatory rituals in Christian churches. During the ritual in those Protestant denominations that perform it, the bread and wine used are believed to be affected to a degree but not fundamentally changed by the ritual. Instead, they serve a symbolic, representational function. The Catholic church, on the other hand, believes that the prayers and rituals of the priest actually bring about an alteration of the substance of the bread and wine, so that they come to share in the essence of Christ's blood and flesh although their outer form remains the same. The more indigenous and traditional a religion, the more its rituals are presentational. The more westernized and liberalized a religion, the more its rituals tend to take on a representational value and function.

Periodic

A periodic ritual is one that is undertaken at regular intervals, such as daily, weekly, monthly, annually, and so forth. The purpose is to mark time, to establish or maintain a connection between the performers and their cultures or communities, and to inspire active and regular participation of members of a tradition in its beliefs and practices. They thereby help to enhance bonds between members of a religious community and their belief system. Such rituals can be either communal or individual and can be performed by the beneficiary or by an officiant. Examples include daily meditation, prayers before meals, Sunday mass, or full moon services.

Imitative or Sympathetic

Imitative or sympathetic rituals are rituals in which participants ceremonially remember or symbolically reenact special events in a religious tradition's sacred past. The Christian practices of baptism and communion, the Jewish Seder, and the annual Muslim pilgrimage to Mecca are some examples. Such rituals may be periodic, as those mentioned above, or may be performed for special occasions. An example of the latter is a ritual of healing, in which a shaman reenacts a past event when a healing occurred or imitates the behavior of a particular spirit whose function it is to dispel disease or disease-causing agents. These rituals have often been labeled "magic" by outsiders to the traditions in which they exist.

Penitential or Corrective

Most religious traditions have specific rituals that serve to cleanse a member of consequences of sins committed, bad karma, or other such actions, and to bring the member back into grace with the divine or spirit world, as well as with the community. Common elements in these include a ritual bath, ascetic practices like fasting, repetition of certain prayers, a period of solitude, and sacrificial offerings. They are to be performed with the hope, but not guarantee, that the supernatural being who is propitiated will grant forgiveness. As such, they are to be performed with an attitude of contrition and humility.

Rites of Passage

Rituals called rites of passage mark one's transition through the various stages in life, from as early as conception throughout life until death, and even afterwards. They mediate and signify changes in individuals' lives, conferring on them identity and status in their communities, taking them from one state of physical and social being to a greater one. At the same time, these rituals validate the traditions, values, and hierarchy of the culture. Drawing on the work of Arnold van Gennep, Victor Turner developed valuable theories with respect to rites of passage. Significant here is his identification of three stages that can be seen in most such rites: the pre-ritual state, the liminal or transitional state, and the post-ritual state.

Puberty rituals are typical of rites of passage and are an important part of many cultures' process of adult identity formation. They function to transition youth from a state of relative freedom and social powerlessness to one of increased power, as well as increased social and familial responsibility. Prior to the puberty ritual, young boys and girls are viewed as children; they generally have few responsibilities or powers and relatively few distinctions. During the liminal state, which can last from a few hours to days or weeks, the youth are separated from the rest of the society and undergo a process whereby they are supposed to let go of their previous state of mind and prepare for their new identity as adults. At the end of the ritual process, the participants emerge with a new identity. Males are often expected to take more responsibility for the support and protection of their families. In many cultures, they

now may be ready for marriage, and they can no longer freely mix with nonrelated females. Likewise, females become of marriage age after puberty, must now dress differently, can no longer play with their friends in the same way, must avoid all but necessary contact with nonrelated males, and so on. They are now women and are expected to fulfill whatever role their cultures assign that state. Thus, puberty rites confer more specified identities, roles, and responsibilities.

Another example of a rite of passage ritual is initiation, or ordination, into a renunciant religious order as a monk or a nun. This is a special ritual, since it is only undertaken by certain members of a culture. It essentially removes them from their families and from the society around them. At the same time, it elevates their status within that society. They are given special privileges as well as special restrictions. Their state can be viewed as one of “extended liminality,” in that they always remain as separate, even when living in the midst of the society. By their leaving the traditional social order in this way, they actually help to validate it. This is because they function to serve as protectors and teachers to those who remain in and support the society.

Arts as Ritual

Dancing, singing or chanting, music, and the various forms of visual art all have religious origins and continue to be integral to most religious traditions. The creation and performance of these are seen as ritual enactments. They are often preceded by rituals of purification, and their performances are believed to bring power or blessedness. As an example, Tibetan Buddhist monks ritually create elaborate *mandalas*, or sacred designs, using colored sand. The ritual is preceded by purification rites over the site and the objects used in creating the *mandala*. The actual creation can take up to a week. Once completed, it is followed by more rituals, and they conclude by sweeping up all the colored sand into an urn. Some of the sand is given to spectators, who see it as sacred and may keep it on their home altars, while the remaining sand is poured into a flowing body of water. The ritual is typically performed to bring healing to the earth. The dismantling of the *mandala* and dispersion of the sand reflects the Buddhist view of impermanence.

Vows and Rituals

Most people who do personal rituals do so as part of a regular adherence to religious beliefs. They typically integrate the rituals into their daily lives, along with eating, working, and so forth. On occasion or for special reasons, individuals may also add vows to their rituals. These take the form of promises to fulfill certain duties or abstain from certain acts for a specified period of time. They are generally done in combination with a vow to perform repeatedly a particular ritual for a certain number of times or days. An example of this is a Christian’s vow of abstinence during Lent along with the performance of specific daily prayers, or a Hindu’s vow to fast on Tuesdays and make specific offerings at a Hanuman temple. Thus, vows and rituals go hand in hand. Moreover, it is believed in many cultural traditions that if one undertakes vows in conjunction with rituals, the latter will be more effective.

Rituals embody the religious tradition of which they are a part. On the empirical level, they facilitate individual identity formation while validating and reaffirming the beliefs, values, and social cohesion and stability of the community. On the spiritual level, they serve as vehicles, in one manner or another, to draw beneficiaries closer to the divine, to enhance communication with spirit beings, to provide access to supernatural powers, or to facilitate one’s path to salvation or enlightenment. Some rituals are seen to have little actual power, while others are believed to be highly efficacious. Traditional cultures tend to place far more emphasis on rituals and their powers. As a consequence, the lives of their adherents are much more ritually defined and supported. Moreover, there is an increasing view that many of the problems in urbanized and westernized society are exacerbated by the lack of ritual tools and supports to address them.

REPRODUCTION

Reproduction in anthropology refers to the processes by which new social members are produced—specifically, the physiological processes of conception, pregnancy, birth, and child raising. In its larger sense, “reproduction” is used to encompass the processes by which societies are reproduced for the future. The term is thus fraught with biological, cultural, and political meanings; power is a central focus in reproductive studies, as those who have the power to influence the process of reproduction can control large populations for better or for worse.

The maturation of the field of the anthropology of reproduction was marked by the publication of *Conceiving the New World Order: The Global Politics of Reproduction*, edited by Faye Ginsburg and Rayna Rapp. This collection expanded the meaning of reproduction into the political arena and generated the interface of reproductive studies with wider issues in the politics of women’s healthcare. From a study of anti-abortion policies in Romania, to China’s one-child policy, to the displacement of thousands of women in India and Pakistan to “purify the national bodies” of both countries, the chapters in this volume called attention to the impact of national and global processes on everyday reproductive experience, most especially through the notion of “stratified reproduction,” which points to transnational reproductive inequalities based on gender, race, and class. In addition, Rayna Rapp’s long-term fieldwork on amniocentesis illustrates racial, class, and religious differences in how women make choices about this uncertain technology and demonstrates the linguistic power of genetic counselors to influence these choices in favor of the culturally approved choice of abortion for genetically defective babies.

Since the 1990s, most anthropological studies of reproduction have focused on what have come to be called “the new reproductive technologies” (NRTs)—technologies designed to intervene in human reproduction. From the birth of the world’s first test-tube baby in 1978 to the cloning of a higher vertebrate from an adult cell in 1997, the rapid expansion of the NRTs in the latter half of the 20th century dramatically redefined the parameters of biological reproduction. The NRTs include, among many others, birth control technologies such as intrauterine devices (IUDs) and the birth control pill; assisted

conception technologies such as artificial insemination and in-vitro fertilization (IVF); screening technologies such as ultrasound, amniocentesis, and blood testing; reparative technologies such as fetal surgeries performed in utero; labor and birth technologies such as electronic fetal monitoring, synthetic hormones for labor induction and augmentation, and multiple types of anesthesia; and postnatal technologies such as infant surgeries and high-tech treatment of babies in neonatal intensive care units. All of these technologies are increasingly affected by developments in biotechnology, such as genetic engineering, which have major implications for the control and management of human fertility.

Like the obstetrical forceps developed by the Chamberlen brothers in the 16th century, the NRTs have double-edged implications for women and their offspring. While those early forceps did save the lives of babies who otherwise might have died, their overzealous and ill-informed application during childbirth by male midwives and obstetricians often left the mother’s body severely damaged and led to increased maternal and fetal morbidity. The NRTs have been equally problematic, often creating as many problems as they solve and causing as much damage as they repair. For example, maternal mortality as a result of ovarian hyperstimulation, and increased congenital abnormality due to multiple births, are but two examples of the “downside” of in-vitro fertilization (IVF).

Reproductive technology has affected every facet of the reproductive process, from preconception onward. To an extent, these developments respond to specific impediments to fertility: IVF, for example, was originally used to assist women with blocked ovarian tubes. Feminist critics, however, have rightly pointed to other, less woman-centered, influences shaping the development of these technologies. For example, Robert Edwards, the research scientist who helped to develop IVF, was trained in embryology and foresaw tremendous research potential from the ability to manipulate the human embryo *ex vivo*. This potential was extensively exploited in the rapid expansion of human embryo experimentation in the 1980s and the 1990s.

The encounter between a largely male medical and scientific establishment and women’s reproductive capacity is very pointed in the context of IVF, which is often represented as being a response to the “desperate” desires of infertile women, but can as readily be

interpreted as a response to the irresistible scientific urge to “unveil” and indeed to redesign “the facts of life.” The tremendous value of early embryonic cells—both commercially and in terms of research—has made IVF an important source of human embryonic stem cells. This fact exists in uneasy tension with women’s demands for improved reproductive services. As in other historical periods, the neglect of women’s reproductive needs is most evident in terms of the kinds of services that will be developed and prioritized. While new embryo therapies are used to detect, and even to eliminate, genetic disease, other reproductive priorities remain devalued and underfunded. For example, while ever more sophisticated technologies are developed to deal with the complications of labor and birth, the normal physiological needs of laboring women remain understudied and unfulfilled. The scientific evidence that does exist supports simple technologies like eating and drinking during labor; woman-centered, supportive care; and upright positions for delivery as being of far more help to birthing women than high-tech machines.

Two major influences continue to shape the development of reproductive technology in ways that are not in women’s interests. One is the continuing, and indeed worsening, effects of global inequality that are borne most heavily by women and young children—especially infants. Adequate, or indeed any, access to basic contraceptive technology remains out of reach of the majority of the world’s female population (despite concerns about population growth, and largely as a result of U.S. anti-abortion policy). Consequently, resource intensive and largely private fertility care is provided to a predominantly wealthy world elite. Meanwhile, enduring tragedies of high maternal and infant mortality due to preventable causes (such as malnutrition and lack of a clean water supply); inadequate access to abortion or contraceptives; and limited, nonexistent, or ineffective reproductive healthcare are the main issues affecting the majority of the world’s women. In sum, proper sanitation, adequate nutrition, improved vaccination programs, access to culturally appropriate forms of birth control, access to community midwives backed by adequate transport systems, and above all, increased literacy and education rates among women remain the most important and life-saving “reproductive technologies.”

At the other end of the spectrum, at the cutting edge of 21st-century medical science, we note the resurgence of a new genetic essentialism. Reproductive technology

is shifting its focus in the direction of germline gene therapies (therapies that can be genetically transmitted because they modify reproductive cells). Annexed to the project of mapping the human genome, reproductive science and medicine are increasingly aimed at both the elimination of genetic pathology and the effort to reengineer the genomes of humans and other life forms. In addition to existing means of technologically assisting conception, the effort to alter human genealogy is the single most important influence on contemporary reproductive technologies. This effort is driven by enormously competitive economic forces, and by an “if we can do it, we must do it” technocratic mentality, resulting in rapidly escalating and largely unregulated technological innovation.

While some commentators argue that reproductive technologies such as the freezing of eggs, cloning by nuclear transfer, germline gene therapy, and embryo biopsy will have a radical effect on gender roles and kinship definitions, the majority of evidence demonstrates a reverse effect: the restabilization of traditional and conservative family ideologies in the face of their potential disruption. At the same time, other influences, such as the lesbian and gay movement, the increase in transnational adoption, rising divorce rates, and greater economic independence for women, have proven more influential in the redefinition of family and parenthood. Consequently, although some uses of reproductive technology have created more parenting options, such as the use of artificial insemination by lesbians, the overwhelming pattern of access to NRTs is defined by the goal of enhancing conventional parenting arrangements by married, heterosexual, and middle-class couples.

Feminist concern about reproductive technologies in the 21st century will increasingly overlap with the criticisms of biotechnology and genetic engineering raised by environmentalists and the general public. Concern about genetically modified organisms in the food chain and in medical applications will increase, particularly as the human-animal border becomes ever more permeable. The extensive feminist literature on NRTs anticipates with great precision many of the profound social, ethical, and political concerns surrounding new forms of genetic and biological determinism arising out of the attempt to alter the human genome. In addition to the effort to redefine medical and scientific priorities in relation to women’s reproductive health worldwide, feminist anthropological scholarship will continue to insist

upon the primacy of fully informed reproductive decision making, in its widest sense, as a fundamental component of human rights.

RESEARCH METHODS

Social science involves the study of people. Social research methods are based on a systematic approach to studying social phenomena. Social sciences include anthropology, sociology, economics, psychology, political science, communications, and history. Researchers in each of these disciplines are interested in pursuing explanations for human social behavior. Sociologists and anthropologists, in particular, are interested in the empirical study of human behavior from a cultural and societal perspective. Oftentimes, social scientists are critiqued for their lack of a vigorous set of research standards that tend to be more apparent in the natural science disciplines. However, social scientists adopt both quantitative and qualitative methodologies by following a measurement process that helps to ensure both reliability and validity in their work. In addition, researchers develop studies that focus on exploratory, descriptive, and explanatory societal questions.

Research Design and Measurement in Social Research

Dimensions of research design include exploration, description, and explanation. Each design supports

different fundamental research goals. Exploratory research is used when the goal is to become familiar with basic facts, people, and concerns. Researchers are often able to develop a well-grounded mental picture of the social situation that is unfolding. Researchers also generate main ideas and develop tentative theories, determine the feasibility of doing additional research, formulate questions and issues for further inquiry, and develop techniques and a sense of direction for research.

Descriptive research is used to provide an accurate profile of a group as well as describe processes, mechanisms, or relationships. In addition, descriptive research gives a verbal or numerical picture of a social setting. Researchers use the descriptive approach to find information to stimulate new explanations; present basic background information or context; create a set of categories and classify types; and clarify a sequence, set of stages, or steps.

Researchers carry out explanatory research when they are interested in solving a problem or establishing an explanation for why something exists as it does. A further goal of explanatory research is to determine the accuracy of a principle or theory. Explanatory research can also be used to find out which competing explanation is better and advance knowledge about an underlying process or social relationship. Explanatory research is especially useful to build or elaborate on a theory so it is more complete, extend a theory or principle into new areas or issues, and provide evidence to support or refute an explanation.

In addition to considering the type of design in social research, researchers must be able to develop measurement standards to establish consistency and accuracy in their concepts. Measurement involves developing a set of clearly defined variables that can be compared and analyzed as precise data points. In order to develop clear, well-defined concepts, researchers must conceptualize and operationalize their variables. Conceptualization involves developing a precise definition of the idea being studied. This definition serves as the standard for empirical measurement in the social world. Without this step, it would be difficult to develop a standard for the concepts being observed. The standard helps to ensure that the measure is observed consistently and accurately throughout the research study.

A second step in the measurement process is operationalization. Researchers operationalize concepts by specifically outlining how the measure will be

Source: © Photo provided by www.downtheroad.org, The Ongoing Global Bicycle Adventure.

tested empirically. In this process, it is imperative that researchers outline data collection steps. How do we capture the concept empirically? Whether we plan to test our concepts using surveys, participant observation, in-depth interviews, archival research, or experiments, we need to clearly establish guidelines for collecting data.

Measurement varies among quantitative and qualitative research designs. The process outlined above tends to be more relevant to quantitative research designs, where the research process is more deductive and linear. In quantitative designs, the researcher usually develops a hypothesis and then seeks empirical observations that either confirm or refute the hypothesis. In contrast, qualitative research designs usually depend on a grounded theory model, where researchers use an inductive approach to developing theoretical explanations. In this case, researchers may develop a research plan that requires they gather empirical evidence prior to developing theoretical statements or hypotheses. These designs tend to be nonlinear and more flexible in how they are carried out.

Proposing Research

Developing a strong research study requires a strong research proposal. Effort spent in this process helps

the researcher outline a research agenda that combines both a discussion of relevant past research and proposed contributions to the field. A proposal should include the following sections: a clear and well-defined research question or problem, a discussion of relevant literature and past research studies, a description of how data will be collected including a discussion of how variables have been conceptualized and operationalized, and a conclusion that includes ethical issues and points for further discussion.

The proposal creates a map of sorts for the researcher to follow. With a well-defined plan of study, the researcher can enter his or her study process with a clear idea of the overall agenda.

Specific Research Designs

Traditionally, social science researchers work with both quantitative and qualitative frameworks. Over time, emphasis has been placed on one research design or the other. However, more recently, there has been a push for collaboration among research designs. Different levels of depth, detail, and understanding can be accomplished through a combination of designs. For example, a field researcher concentrating on participant observation can collect rich, detailed descriptions of what she sees in the field, but may not have the data in a format that allows for any quantification for comparison. By including a survey tool, she can then compare basic demographic characteristics or other data that suits her research needs. Triangulation of methods has become accepted practice. Most social scientists agree that a combination of methods assists in helping to ensure validity and reliability.

Because of the nature of the data that is collected, most research methods are inherently quantitative or qualitative. Quantitative methods include survey research, secondary analysis, existing statistical analysis,

and experiments. Qualitative methods include field research, historical comparative research, and natural experiments. Focus groups, case studies, and content analysis can be used as either quantitative or qualitative depending on how they are employed and the suitability of the research question.

Consistently increasing in the use since the 1930s and the development of George Gallup's Gallup Poll, survey research is one of the most popular means of collecting data in the social sciences. If they are directed to a representative target population, surveys have shown to be useful in measuring popular opinion. Surveys are also used to measure attitude, behavior, knowledge, and consumer preference. Popular tools across the social sciences, surveys provide large amounts of data that can be gathered quickly, are relatively inexpensive to collect, and are easily quantified to be used for statistical analysis.

However, there are drawbacks to this method as well. Because most surveys consist of close-ended questions, the depth and breadth of the response is limited. Respondents may be choosing the 'best' response, though it may not truly represent their feelings or ideas. In addition, survey analysts have to account for a standard margin of error that can be derived from analyzing cases of missing responses, deceit, or simply misunderstanding the nature of the question.

Two additional quantitative methods that are often used in conjunction are secondary analysis and existing statistics. Each method relies on past collection of data. Secondary analysis is used when a researcher is interested in re-analyzing a study that has already been carried out. This occurs to offer a test of reliability of the study but can also serve as a means to test other cause-and-effect relationships or theoretical explanations of the variables.

Using existing statistics is slightly different. In this method, researchers are not collecting the data first hand either, but instead develop their own analytic schemata for data that has been compiled by another source. For example, researchers use U.S. Census data to analyze educational attainment by neighborhood by using zip code aggregate data and educational attainment rates by high school.

The experimental method is used most often in psychology but has been used to isolate causal factors in both sociology and anthropology. Used to isolate factors of cause-and-effect relationships, experiments are highly detailed in their design and rely on the

researcher's ability to test for validity through control of the experiment conditions. Most experiments in the social sciences rely on a controlled, simulated environment, where participants are observed before and after a change to the independent variable.

Qualitative methods differ in that the form of data is not numeric but highly detailed and relies on an incorporation of thematic analysis and empirical observation. Examples of data include, but are not limited to, interview transcriptions, maps, photographs, diaries or journals, oral histories, and document analysis. Common qualitative methods include field research, historical comparative research, and natural experiments.

Field research is based on techniques of observation and analysis in a natural setting. The goal of field research is to capture a real picture of human social behavior. In order to do this, researchers study groups and individuals in their natural social settings. Researchers can take on numerous roles in the field. Roles are categorized by four distinctions: participant observer, complete participant, complete observer, and observer participant. As participant observer, the researcher acts as a pseudomember of the group. Members are aware of the researcher's role and recognize the duality of their responsibility as participant and observer. When the researcher acts as a complete participant she acts as a member of the group, keeping her identity as a researcher hidden from the group. There is some question as to what level of deception is acceptable. As a complete observer, the researcher remains undetected and unnoticed, reporting observations. The fourth role the researcher assumes is the observer as participant. In this situation, the researcher is a known, overt observer, however she has limited contact with members. She remains slightly detached from the group, which some argue allows for greater objectivity.

Two issues emerge in terms of validity of field research data. Researchers need to consider internal consistency, or whether the data are plausible given all that is known about a person, group, or event, not considering forms of human deception. External consistency, or whether observations and data can be verified or cross-checked with other sources of data, needs to be considered as well. Both of these issues rest with the research design and operationalization of the research question.

Historical comparative research is another form of qualitative research. Sources for this data include

archives, library collections, and memory studies. Historical comparative researchers look for three things in their evidence: implicit conceptual framework, particular details, and empirical generalizations. The conceptual framework should include an implicit understanding of assumptions and perspective of the person reporting events. Researchers need to take careful consideration of times, dates, events, chronology, people involved, and locations. It is essential that researchers try to verify information by focusing on factual statements on which there is agreement. However, consideration must be taken to ensure that data is valid and not simply the result of a hidden historical agenda. The researcher is also interested in interpretations of evidence and the “silences” or cases where the evidence fails to address a particular event, topic, or issue.

Ethical Issues

Researchers need to be aware of their own cultural biases. Without this awareness, judgments of other cultures may be made that jeopardize the validity of the data. Even though it is difficult at times, one way to do this is to defocus before entering the field. This step involves figuratively removing oneself from the primary focus of the research paradigm. The goal is to remain open to everything one may encounter and to not take occurrences for granted but to acknowledge everything as potentially important and meaningful.

Social research methods allow us to provide explanations of human social behavior. Through a systematic approach, researchers can begin to make sense of the social world. Although some disciplines focus on particular methods over others (psychology: experiments; sociology: surveys; anthropology: field research), each takes into account the goals of the discipline in an effort to collect the most reliable and valid results possible.

RESEARCH IN ANTHROPOLOGY

Anthropology has for many years studied social cultures, beginning with the civilized societies studying the cultures of the not-so-civilized in undeveloped areas. In recent years, the role of anthropology has been reevaluated and changes have been made. Today's anthropologists are using more of an interdisciplinary approach, which helps in understanding human motives and capabilities. Anthropology has broadened to include the areas of development, tourism, emotions, ethnicity, and global systems.

In the past two decades, anthropology has taken on many areas of specialization. For example, scientists specialize in such topics as agriculture, education, the environment, feminism, nutrition, and urban issues. Others focus on a certain geographic area, such as Africa, Europe, the Middle East, or North America. Independent self-sufficient cultures, which have been the focus of traditional anthropology, no longer exist. Trends now are toward studying urban areas and global issues. Some anthropologists have moved into a new area of research known as cultural studies. Others continue to use the more traditional methods of research. This type of work is now called applied anthropology.

Anthropology was traditionally associated with colonialism, as many studies took place in undeveloped areas. Most anthropological research and writing was done by white Europeans and Americans. This is changing, as people from all cultural backgrounds are beginning to work in anthropology and cultural studies. Within the framework of applied anthropology, scientists are increasingly attempting to use their research skills to help solve important world problems.

After World War II, many colonies received their independence. The subdiscipline of development anthropology has helped small societies to adjust to the changes that came with independence. Groups of indigenous peoples have also begun to organize in an attempt to better their conditions and defend their rights to the land and natural resources. Many anthropologists have become advocates for these groups. Some Native American tribes have hired anthropologists to help them protect their cultural heritage. In some cases, Native Americans are working as anthropologists themselves, in order to help their tribes.

More and more anthropologists have become interested in poverty, violence, and injustice. Some have helped human rights organizations to excavate and identify remains of people killed in ethnic and political mass killings. They have helped bring some of the perpetrators to justice in such places as El Salvador, Rwanda, and the former Yugoslavia.

In some areas of the world, governments are hiring subsistence farmers to grow crops for export. Anthropologists who specialize in nutrition and health have shown that rather than helping, these changes have increased poverty, malnutrition, and infant mortality. In the United States, factory closings and outsourcing have been studied by anthropologists. They hope the results of their research will show businesses and governments the potential negative effects of these actions. As times have changed, so has anthropology.

— Pat McCarthy

REVITALIZATION MOVEMENTS

Anthropologists such as Anthony F. C. Wallace first employed the term revitalization movement in 1956. The term was created to explain how a society functions under severe stress. A movement would arise because of the complete disorganization and conflict within a society and the need for reform and transformation. Wallace explained that when members of a society feel that their needs are not being satisfied, this

process enables them to reorganize and reestablish a more fulfilling culture. Usually, revitalization movements have a religious factor, but they may be pursued from a political stance. Religious revitalization movements frequently occurred in indigenous or traditional societies during colonial times and from first European contact. Other social movements and organizations that have been closely associated with revitalization movements include Cargo Cults, *Terre sans mal* movements, Madhist movements, Millenarian movements, Messianic movements, Nativistic movements, and separatist churches.

In his book *Religion: An Anthropological View*, Wallace stresses two aims for a revitalization movement: to provide “immediate salvation to the presently afflicted” and “to reorganize the culture in such a manner that a better way of life is brought into being to take the place of the old.”

A revitalization movement has five stages. The first stage is called “The Steady Stage.” It is characterized by small amounts of stress and disorganization within the society. There may be a number of incidents where deviance occurs; this is thought to be caused by society’s penalty for the current situation. The second stage is called “The Period of Increased Individual Stress.” The equilibrium becomes insecure and unsteady within the social system. Disease, war, social subordination, and acculturation arise, which leaves individuals uneasy and under a great deal of stress. Individuals feel that society has failed them and blame the current system. Crime and illness are significantly present even though the situation is still regarded as a temporary glitch in the system. “The Period of Cultural Distortion” is the next stage. Individual members of society attempt to take control of their lives by using self-destructive means such as drinking, gambling, sexual discrepancies, and attacking public figures in the community. Previously prominent individuals in the community begin to lose hope of reviving the community.

The fourth stage is “The Period of Revitalization.” Without the completion of this stage, the culture will die out, split into smaller groups with similar attributes, or integrate into another, more secure and stable society. There are six criteria that are associated with this stage. There must be the construction of a new order. This could be through formulation of a new religion, political system, or social organization, which becomes the central focus for achieving a superior society including a more profitable way of

life. The initiative is to have an ideal system to work towards that can easily be contrasted to the present, unsuccessful system.

There is a specific routine or set of instructions that are followed in order to achieve this society. These steps promote a renewed sense of hope and confidence in the future. The next criterion involves communicating the message of this new culture or institution to others. The individuals who were the founders of this new ideal society must find ways to spread the news of their new code. They attempt to draw in as many people as possible who will follow and obey their code. The main attraction of this culture is the reassurance that it will lead the population to stability, organization, and salvation.

Organization is an important criterion within the revitalization. Society must be structured with the official who established this “utopian society” present. There must be a group of individuals who organize and delegate the mass with followers who will listen and follow instructions. These groups are referred to as disciples and their followers. The disciples insure that the movement towards their goal is in progress while the followers participate in the existing society supporting the disciples. The criterion involves adaptation. The disciples must be able to deal with and adapt to any flaws in their new system. This may include modifying the existing strategies within the code to defend the end product of the cultural revitalization. The followers must believe that this movement is truly for the best. Individuals who do not follow the code are referred to as deviant, or more severely, enemies of the state.

The last criterion of the Period of Revitalization is routinization. This criterion places emphasis on maintaining society’s transformation. There is no longer a need to convert individuals. Maintenance occurs through ritual, myth, and the recollection of why their society has transformed. Order and morale must be preserved within the social, political, and religious segments. The final stage of the revitalization movement is “The New Steady State.” Any changes that must be made to the code in order to keep equilibrium within the culture must be recognized. This may involve altering the focus of values to meet the needs of an ever-changing society. As ideas evolve, cultures evolve as well.

Past revitalization movements include the Cargo Cults in Melanesia, *Terre sans mal* movements in the South American tropical forest, Madhist movements

in Islamic areas, Millenarian movements in Christian areas, Messianic movements in Judaic areas, Nativistic movements among the North American Indians, and Separatist churches among African Americans. There are four main attributes of these revitalization movements: revivalistic characteristics, as seen with the Ghost Dance; utopian characteristics, as seen with the *Terre sans mal* movements; assimilative characteristics, as seen with the American civil rights movements; and finally, expropriative characteristics, as seen with the Cargo Cults.

RITES OF PASSAGE

Variously known as “life crisis” ceremonies, rites of passage, or by the French term *rites de passage*, this complex of practices includes birthing, coming of age, commencement exercises, marriage, ordination, recruitment into secret societies or military formations, accession to high office, and mortuary processes. In all known human societies, rituals of status transition are highly organized and consume considerable material resources and social energy.

For nearly a century, anthropological approaches to rites of passage have been profoundly influenced by Van Gennep’s classic proto-structuralist model of the “tripartite” structure of these commonly occurring rituals, a formulation that has shown remarkable resilience and longevity in the intellectual history of the discipline. According to Van Gennep, and as famously developed by Victor Turner, such rites

commence with the radical separation of the person or persons being transformed, often marked through special adornment, locale, or comportment. The subject then enters into a special interstitial or intermediate state—in Turner’s terms, “betwixt and between” conventional social statuses or categories—in which he or she is neither student nor graduate, child nor adult, unmarried nor married, layman nor priest, heir-apparent nor king. During this “liminal period,” the person undergoing ritual transformation is often subject to special prohibitions and precau-

Source: © iStockphoto/Israel Talby.

tions; he or she may be apprehended as especially pure, sacred, stigmatized, or polluted and may be subjected to pain, humiliation, and heightened risks. The person undergoing such a transformative rite is often, in effect, reduced to a subordinate or fluid state subjected to collectively imposed refashioning. This in-between period is often characterized by paradoxical or dramatic reversals of ordinary behavior, often involving real or symbolic violence, exaggerated humor, and carnivalesque elaboration of the lower half of the body; one needs, in effect, to step outside of normal society and socialized frameworks in order to alter one’s social position. In the final stage of reaggregation, during which basic principles of social life are celebrated or reinvigorated, the subject is reintegrated into normal life, usually into a different (often higher-ranked) social role than that occupied before the rite.

Initiation rites, among the most highly elaborated rites of passage, often emphasize the detachment of the initiate from his or her prior links to childhood and exclusively domestic realms by incorporating images of birth and death; they often involve the physical isolation of initiates, often according to principles of strict gender segregation, as well as practices of physical incision, quite literally “cutting” earlier bonds by rupturing the body’s surfaces. Often, initiatory cutting is directed towards the organs of generation

(the male foreskin, or, less commonly, the female clitoris or labia), signaling, in part, that sexual pleasure and libidinal drives are henceforth to be subordinated to larger, collectively regulated projects of social and symbolic reproduction. Such rites may, at the manifest level, intensify categorical distinctions between human and animal, as well as male and female, while at other levels blurring or transcending these contrastive schemes.

Their tripartite sequence, the extraordinary qualities of the liminal phase, and the bodily symbolism of radical transformation render rites of passage highly appropriate for dramatizing transformations in persons other than the rite’s formal subjects. Those organizing, performing, or attending the ritual often take on certain liminal, interstitial qualities during the ceremony and undergo significant (if subtle or backgrounded) transformations and shifts in status. Rites of passage are thus nearly always collective enterprises that proceed upon multiple tracks, establishing important connections and distinctions among varied persons and groups beyond the proximate, central foci of ritual attention.

For example, the rites of christening or bris (the Jewish circumcision), while manifestly directed towards transforming the moral and spiritual status of the infant, also confirm or help establish important shifts in other persons’ conditions, especially in the

generations of the child's parents and grandparents. The parents are established in front of the family and the religious community as persons of tradition, substance, and faith. Grandparents from both sides of the family are, if possible, prominent at a christening, and often exhibit considerably warmer, less formal relations with one another than they did at the wedding. At the Jewish bris, the paternal grandfather often holds his grandson as the foreskin is excised, evoking a line of patriarchal authority that in principle stretches back through the generations to the original covenant between the Lord and His chosen people. In this ambiguous liminal position, holding his male flesh and blood under the knife, the grandfather takes on aspects of the early patriarchs themselves, recalling Abraham's abortive sacrifice of Isaac and Moses' role as the first circumciser. In this sense, the bris is equally a rite of passage for the grandfather and his grandson, who emerge from it confirmed respectively as patriarch and novice within the family and the wider community; as a reenactment of the mythic forging of the covenant between Yaweh and his chosen people, each bris also celebrates the collective solidarity of the Jewish community.

At the end of the life cycle in modern American society, the funeral orchestrates another set of complex social and temporal relationships. The dead person may be thought of as moving from initial separation (through special treatment, including embalming), into the ambiguous liminal status of funeral corpse, to a final state of integration into the domain of the dead (signified by burial or cremation). This close attention to the dead body not only manages the deceased's social transition out of the living world, but separates the mourners as a collective social unit out of ordinary life, placing them into an ambiguous interstitial space and time. They wear special somber clothes, adopt a solemn demeanor, and may even be expected to view or kiss the corpse, before the coffin lid is closed and the service begins. At the rite's conclusion, they are collectively reintegrated into ordinary life, often through actions such as food consumption and lively conversation at a reception, that emphasize the renewal of life.

The ultimate consequence of the funeral's double tripartite structure is an achieved marked separation between the categories of life and death. Paradoxically, this ritual distance enables subsequent moments of communion between the living and the dead, as in visits to the cemetery, which are often tied to key

moments in the annual calendar, such as Christmas, Memorial Day, or Mother's Day.

In an important reformulation of previous approaches, Terry Turner argues that the intermediate or liminal phase of such rites is characterized not so much by "anti-structure," as by a kind of hyper-structuration, enabling a kind of regimenting or reconceptualization of the opening and closing phases of the ritual process. The associated cognitive and affective transformations may not necessarily be immediately accessible to the putative subjects of initiation rites (who may primarily experience terror, discomfort, and disorientation during the ceremony itself); indeed, the underlying structural logic of the key transformations may only become apparent to actors later in the life cycle, as they initiate subsequent cohorts or generations.

Precisely because rites of passage have such profound implications for the reproduction of social formations as well as for the refashioning of individual selfhood, these ritual complexes are often subject to intense political struggle and may emerge as arenas through which history is actively made. Nguni state formation in the early 19th century, for example, was predicated on the suppression of circumcision lodges through which local lineages reproduced themselves, in favor of higher-order recruitment into cross-cutting military regiments. Lincoln's Gettysburg address, a closing oration in an extended mass mortuary process, occasioned the collective reimagining of American democracy, catalyzing and codifying an extended historical transformation that is still being played out to this day. North American society in the early 21st century is gripped by bitter debates over gay marriage, an issue arguably capable of determining the course of national elections. At stake in the organization and evaluation of rites of passage, it would appear, are the constitutive principles upon which human collective life is founded, contested, and potentially remade.

RIVERS, W. H. R. (1864–1922)

William Halse Rivers was an unusual talent who made significant contributions both to psychology and anthropology, although his reputation has survived best in anthropology, particularly in the field of social organization.

Rivers was the eldest of four children born to Henry, an Anglican churchman and speech therapist, and Elizabeth Rivers. His education was interrupted by ill-health and a serious stammer, and when typhoid fever prevented him sitting for his exam for Cambridge, he switched to medicine. In 1886, Rivers graduated bachelor of medicine from the University of London, the youngest graduate from Bartholomew's Hospital for almost a century. After service as a ship's surgeon, Rivers gained his MD from London in 1888 and was elected Fellow of the Royal College of Physicians. In 1893 he was appointed Lecturer in Psychological and Experimental Psychology at Cambridge.

In 1898, Rivers took part in an expedition to an island group in the Torres Straits, between Australia and Papua New Guinea. He was invited to take part by virtue of his role as a prominent psychologist. After refusing the offer, Rivers eventually decided to go, kindling his lifelong interest in anthropology in the process. He made a second trip in 1901 and in 1902 went to Melanesia, and also studied the Todas of south-western India. His book *The Todas* (1906), the result of that expedition, is widely regarded as a classic.

Through all this, Rivers retained his interest in psychology. Between 1903 and 1907, Rivers and a colleague, Henry Head, took part in a protracted experiment on the peripheral sensory mechanism. The experiment involved cutting two cutaneous nerves in Head's left forearm and mapping the process toward the full recovery of skin sensitivity. While the conclusions of the study have risen and fallen in esteem, the

value of the experiment and the conditions under which it was performed have had a long influence. A feature of Rivers's career was his attention to the requirements of methodology.

In 1904, Rivers cooperated with his friend C. S. Myers and the venerable James Ward to found the *British Journal of Psychology*. This was an important milestone for the development of independent British psychology.

In November 1907, Rivers took an extended trip to the Solomon Islands, later extended to Melanesia. The trip lasted about a year. Soon after his return, he was elected a Fellow of the Royal Society, along with Bertrand Russell.

When Rivers began *The History of Melanesian Society* (1914), he was thinking about social development in evolutionary terms, but while writing that work, he came to stress the important role even small groups of immigrants could have, changes which could in all likelihood quickly look like evolutionary changes. This led him to adopt the diffusionist views championed by his Cambridge colleague, the Australian-born ethnologist Grafton Elliot Smith. Rivers regarded *The History of Melanesian Society* as his magnum opus, but it has not had the influence of other works like *Kinship and Social Organization* (1914). Many regard Rivers's main contribution to be the study of social organization.

In July 1915, soon after his return from a third expedition to Australasia, Rivers returned to medicine. After a year at a military hospital in Lancashire as a civilian physician, he was commissioned in 1917 into the Royal Army Medical Corps with the rank of captain and sent to Craiglockhart Hospital, near Edinburgh in Scotland. While there, Rivers had responsibility for counseling Siegfried Sassoon. The two became close friends, even though Rivers was ambivalent about his role in coaxing Sassoon back to the front. For his part, Sassoon never forgot Rivers's kindness and fatherly attention to his welfare. They remained in close touch for the remainder of Rivers's life.

After the war, Rivers returned to Cambridge where he concentrated on his work in psychology, psychiatry, sociology, and ethnology, stressing the interrelationships among them. He served as first president of the medical section of the newly formed British Psychoanalytical Society. In opposition to the mainstream psychoanalysis, he emphasized the role of fear as a primary psychological motivation. He preferred to speak of "the unwitting" to the unconscious, and

disagreed with Freud and Jung over the alleged universality of symbols. Rivers's academic respectability helped psychoanalysis acquire an audience in Britain.

Rivers died unexpectedly on June 4, 1922 from a strangulated hernia. At the time of his death he was the Labor Party candidate for the University of London.

RNA MOLECULE

RNA (ribonucleic acid) is a single-stranded nucleic acid. This molecule is involved in protein synthesis.

There are several types of RNA:

mRNA: This is messenger RNA, which serves as a code for proteins. It does this by carrying information in what are called “codons” or a “triplet code” that is specific for a particular amino acid.

rRNA: This is ribosomal RNA, which forms the basic structure of the ribosomes. rRNA also catalyzes protein synthesis.

tRNA: This is transfer RNA, which serves as an adaptor between mRNA and amino acids. One end of the tRNA has an “anti-codon” that matches with the mRNAs codon; the other end has an amino acid attached.

snRNA: This is small nuclear RNA, which serves to function in a variety of nuclear processes, as well as structural and catalytic roles, mainly the splicing of pre-mRNA.

snoRNA: This is small nuclear RNA, which is involved in processing and chemically modifying rRNA.

hnRNA: This is heterogeneous nuclear RNA, which is pre-mRNA that contains noncoding regions (called introns) that separate coding regions (called exons).

Other noncoding RNAs: These RNAs function in other diverse cellular processes, including X-chromosome inactivation, telomere synthesis, and the transportation of unprocessed proteins to the endoplasmic reticulum.

Compared with the DNA molecule, the RNA molecule has some basic differences in structure. The two molecules have many of the same nucleotides: adenine, guanine, and cytosine. However, only DNA has thymine, whereas RNA contains uracil instead. Another major difference is in the sugar that makes up the phosphate backbone. The DNA molecule contains deoxyribose, whereas the RNA molecule contains ribose. In addition, they both have functional differences; RNA synthesizes proteins, whereas DNA synthesizes RNA.

The RNA molecule, initially, may sound like a small insignificant molecule; however, it is capable of supporting extremely small and simple life forms called “viruses.” The viral genome can be made up of RNA (single-stranded or double-stranded), or DNA (also single-stranded or double-stranded). Viruses are called “obligate intracellular parasites,” because they need to use the host’s enzymes and ribosomes in order to synthesize copies of their own genomes. Also, viruses are not actually cells; rather, they consist only of nucleic acid enclosed in a protein shell, called a “capsid,” and they need to infect a host cell they replicate.

The prevailing belief in modern science is that RNA was most likely the first genetic material to exist. In a primordial sense, the formation of genetic information would have made it possible for molecular aggregates (precursors to simple cells) to pass along not only transient samples of molecules, but more specifically, permanent molecular instructions to make more of these molecules.

During the process of transcription, DNA produces RNA, and during the process of translation, RNA (along with ribosomes, which are also made of RNA) produces proteins (both structural proteins and enzymes). These processes involve intricate machinery, which could not have evolved all at once. However, it is conceivable that it did emerge from a simpler process. Therefore, prior to the existence of DNA, a more primitive mechanism involving the

alignment of amino acids along strands of RNA could have existed. Consequently, the first “genes” were most likely not the more organized DNA molecule, rather short strands of RNA that could have self-replicated in a prebiotic environment.

In the 1980s, a scientist by the name of Thomas Cech proved that RNA molecules were important catalysts in eukaryotic cells. This discovery extinguished the axiom that only proteins could act as a biological catalyst. Cech and other researchers discovered “ribozymes,” which help to catalyze the synthesis of new mRNA, tRNA, and rRNA. Taking this into account, it can be visualized that RNA could have been autocatalytic and capable of consistent self-replication in a prebiotic environment long before proteins, enzymes, or DNA existed.

It is well established that the DNA molecule is a far more stable repository than the RNA molecule for the storage of genetic material. Conceivably, once DNA molecules evolved, RNA molecules maintained their primitive role as intermediates in the translation of genetic expression. Consequently, the DNA molecule became the storage center that can synthesize mRNA. However, the model provided by the RNA molecule paved the way for the DNA molecule.

ROBBINS, RICHARD H. (1940–)

Richard Robbins is currently the SUNY Distinguished Teaching Professor at State University of New York, Plattsburgh. Robbins earned his BA in psychology at

Rutgers University in 1961, an MA in anthropology at New York University, New York in 1964, and a PhD in anthropology at the University of North Carolina, Chapel Hill in 1970. Professor Robbins' contributions to anthropology are in the areas of globalization, applied anthropology, public policy, and teaching. His publications reflect his strong commitment to and success in teaching undergraduate anthropology. Robbins has earned many honors and awards for teaching including the Outstanding Academic Title of the year award in 1999 for his text *Global Problems and the Culture of Capitalism*. He was also the recipient of the 1994 Textbook and Academic Authors Association Excellence Award for the outstanding text in the social sciences and humanities, *Cultural Anthropology: A Problem-Based Approach*.

Robbins's field research and publications include studies of suicide among the Naskapi Indians of Quebec, political change among the Cree Indians on Hudson's Bay, and the social and economic history of an Acadian fishing village in New Brunswick. Robbins's contributions to teaching, however, most distinguish his career. He has worked to improve undergraduate education and to enhance collaborative writing through computer software and Internet sites. He has also contributed to the Consortium for International Cooperation in Higher Education and the National Endowment for the Humanities as a consultant for the development of general education. Robbins regularly presents papers on teaching science and anthropology, collaborative learning, the foundations of an undergraduate education, and education and cultural change. His textbooks focus on developing citizen-activist students who can examine the policy and cultural changes needed to address contemporary global problems.

ROCK ART

Rock art is painted, engraved, or scratched elements (signs, figures, writings) on rocky surfaces such as open-air rocks, caves, decorated menhir, boulders, and slabs. It may also include portable art and other forms of artistic representations of prehistoric populations. Often it is identified with cave art. The scientific study of rock art using archaeological methods is known as rupestrian archaeology.

Traditionally, engraving, bas-relief, graphics, and painting are considered the main genres of monumental rock art and mobile art (small artistic objects made of stone, bone, antler, or images on tools, everyday items, musical instruments, decorations, etc.). Both monumental and mobile rock art can be divided into two categories: animalistic (predominant in monumental art) and anthropomorphic (represented mainly in statuettes), which exist in three main forms: realistic (or naturalistic), ornamental, and gesture (singing).

The most striking examples of rock painting are found in the Pyrenees; complex polychromatic animal paintings decorate the caves at Lascaux, Montespan, and Trois Frères in France and Altamira in Spain. Such traits as three-dimensionality, perspective, proportion of items and their elements, and the impression of movement are typical of them. Sometimes connections between several images (animalistic and others) can be traced; a few may illustrate the development of a situation over time. Impressive scenes of hunting dominate in animalistic painting; it has become the background for a series of theories of the function of rock art in prehistoric culture. Human presence in rock art painting is usually conveyed by a series of signs symbolizing anthropogenic impact on the animal (images of human weapons, animal injuries, human hands on the animal images, etc.)

Characteristic woman statuettes with exaggerated features of fertility (often called Paleolithic Venus)

are a most peculiar form of mobile art. Their finds are connected mainly with Central Europe (Pavlov, Dolni Vestonice) and the Kostenki region of Russia and Middle Dnipro area of Ukraine (Mezin, Mezhirichi). They are made of soft stone (such as loess, sandstone, talc); most of them are schematic, with no portrait traits or any other personal features.

The first attempts at artistic activity date to the Early Paleolithic (Acheulean and Mousterian) period and are considered the result of experiencing the natural environment. Straight, curved, and wavy lines scratched or engraved on tubular bones, ribs, antlers, pebbles, and stone (mostly chalkstone and sandstone) are associated with this stage. Later, handprints and “macaroni” forms of artificial sign appear. The general development of rock art can be represented by the following chronology:

1. 32,000–27,000 BC: few images of heads or front parts of animals;
2. 26,000–22,000 BC: origin of sculpture and painting;
3. 21,000–17,000 BC: gradual improvement of all genres;
4. 16,000–10,000 BC: golden age of rock art;
5. 10,000–6,000 BC: simplification and schematization of painting.

The general evolution of rock art was a gradual transition from simple painted or engraved lines, or

Source: © iStockphoto/Matthew Scherf.

representations of animal or human fragments, at the beginning of the Upper Paleolithic period, to complex polychromatic compositions at the end of the Upper Paleolithic period, to simplified schematic images during the Mesolithic period.

Rock art in different parts of Europe differs in artistic object, composition, and technique as well as forms and styles. The Franco-Cantabrian region is known for caves with realistic painting and engraving (Altamira, Lascaux, Nio, etc.). The Mediterranean (Italy, southern France, and southeastern Spain) is characterized by relatively more schematic images alongside numerous human handprints on cave walls (Balzi Rossi, Trois Freres, La Madelein, Font-de-Gaume). Some regard this as a unique area or as a special stage of rock art evolution. Eastern Europe (Central Europe and Siberia) is characterized by highly developed mobile art (including Paleolithic Venus) and bone ornamentals.

ROLE AND STATUS

The script that an actor followed was once written on a roll of paper, and the part played became known as a “role.” As Shakespeare famously wrote, “All the world’s a stage, and all the men and women merely players.” Sociologists define “role” as a combination of expected behaviors in a socially understood situation.

Closely related to social roles is the concept of status. Status refers to a social position, that is, the social niche people occupy in relation to others. A distinction is usually made between “ascribed” and “achieved”

status. Ascribed status is assigned, often on the basis of birth, with age and sex being important markers and with some societies using perceived “race” and ethnicity to assign status. Achieved status is attained through the behavior of an individual, often in terms of occupation and skills. As Ralph Linton pointed out, one occupies a certain status while one plays a particular role.

For example, most people know me as an anthropologist at a university where I teach, read and write, attend meetings, and occasionally do fieldwork. I play the roles of instructor, researcher, colleague, and ethnographer, and my achieved status is fairly high. Within my kinship system where I have a mostly ascribed status, I am a son, brother, brother-in-law, nephew, uncle, husband, father, grandfather. In the schools, I play the role of secretary of the PTA and occasional speaker. Within one very small group, I am a less than mediocre archer, and there I have a low status.

People define roles for themselves and attempt to achieve a certain status through playing that role, but if their attempt is not socially accepted, they will not achieve that status. For example, a person may attempt the role of a prophet by preaching on street corners, but if others do not gather to listen, he will attain little or no status and presumably will eventually abandon that role.

Indeed, people form expectations about the roles that will be played both by themselves and others. The surrounding social world contains many clues, some subtle and some obvious, that encourage everyone to act within the expectations that others have for them. The status attached to these roles will come largely from their predetermined societal evaluation.

The term *role confusion* refers to a situation in which people have difficulty determining what role they should play and is usually divided into *role strain* and *role conflict*. Role strain occurs within the same role set; for example, in a large family gathering a person may feel conflicted among playing the roles of uncle, husband, or son-in-law. Role conflict occurs across different role sets; for example, if a person’s son is in one of her university classes, she may feel conflicted between the roles of mother and instructor.

The traditional concept of role is rather too rigid for use in contemporary social and behavior sciences and has been modified by the inclusion of the concept of self-identity, which allows actors to simultaneously express their selves and fulfill their roles.

— Robert Lawless

 ROME, ANCIENT

Rome and its vast literature and civilization formed the point of departure for scholarly investigation during the 19th century beginnings of anthropology, archaeology, and sociology. At the time, university admission required the knowledge of both Latin and Greek. This educational practice had begun during the Renaissance and was only dropped during the mid-1960s in Europe. For many, Greek and Roman civilizations were the first “alien” civilizations encountered.

The history of Rome and its empire covers over a thousand years. From obscure, mythical beginnings, Rome went on to rule the ancient world. Its political power and cultural influence reached beyond its well-defended borders and were supported by the way Roman society was organized and by its (initially) generous treatment of its allies. Between approximately 600 BCE and 200 BCE, a long-running struggle took place between the patricians and the *plebs*, and a republic of sorts emerged, which lasted in name until 44 BCE, when a battle for ultimate power arose among the patrician generals. Rome became an empire that relied on military strongmen to defend its interests and to pursue the expansion of its territory to support the center. In the fifth century CE, the western Roman Empire fragmented under the joint pressures of barbarian invasions and internal economic weakness.

Roman Social History

Rome was situated at an important river crossing approximately 17 miles inland from the mouth of the Tiber, and thus was in a position to control trade into the back country. The city had a mixed population of locals and foreigners from its very beginnings.

The common inhabitants of Rome were originally divided into three *tribes* (either related to the root “tres”—three—or thought to derive from “trifu,” a term used on some second century BCE bronze tablets found in Umbria, where it appears to mean “community”). Later, more tribes were created to accommodate the inhabitants of the incorporated territories, those where Roman citizens had settled or whose original population had been incorporated as citizens. There were always four tribes for the city of Rome, and, ultimately, 31 “rustic” ones. Every citizen had to belong to a tribe, and personal names would be ordered as follows: first or given name; then the family name or, in the case of patricians, the name of the *gens* (clan); next the name of the father; then the name of the voting tribe; and last, a *cognomen*, frequently an optional nickname. The standard example is always Marcus (*preanomen*) Tullius (his *gens*) Marci filius (son of Marcus) Cornelia tribu (voting tribe) Cicero (cognomen). Later, these *cognomina* became more popular than the first or given names, and during the empire even the *plebs* began to use them.

Roman citizens were also divided according to wealth into a *classis* (group or class; plural: *classes*); the two classes were those who could afford to arm themselves and the rest, who could not. During the fifth century, at the time of the Middle Republic, this rough division was refined into five *classes*: three that functioned as heavy infantry, and two as skirmishers. During the Late Republic, the division into *classes* was also used for tax purposes. Until 167 BCE all individuals had to pay *tributum* or direct taxes, an amount that could vary from year to year according to the needs of the state. After that date, all citizens, inhabitants of Italian *coloniae* or Italy itself, were exempt: the wealth that came from the provinces, which were under direct government of the Roman state, was sufficient.

Decisions about which class one belonged to were in the hands of two patrician *censors* (later plebeians were eligible as well), who conducted a *census* every four or five years. Those who were too poor to contribute in any way to the well-being of the state were called “proletarians” because the only thing they provided was their *proles*, or offspring. The *classes* similarly served to assign people to voting groups that made up the original assembly, the *comitia centuriata*. The majority within each group decided the vote for that group. The voting system in Rome was more complex than described here, but it appears to have

been weighted in such a way that the aristocracy could outvote the plebs and the old the young. During the Late Republic and imperial times, the *censors* also judged people's morals and could remove those they objected to from the voting rolls. Censuses were conducted not only in Italy but also in the provinces and colonies.

The *plebs* consisted of all those who were not of patrician descent. Originally, members of the *plebs* were not allowed to hold religious positions and were excluded from the senate and magistracies and forbidden to intermarry with patricians, but they did have to serve (if they could afford it) in the army. During the Conflict of the Orders, a period of approximately 200 years, the *plebs* organized itself, and set up a parallel government on various occasions. *Secessio*, where the entire *plebs* of Rome would leave the city, occurred several times: gained were inviolability for its officers, the *tribunes*, and a host of other benefits and laws as well as political equality with the aristocrats for the wealthier among them. Eventually, the rights and officers were absorbed into the larger structure of the government of the *populus Romanus*.

It is calculated that slaves made up approximately 10% of the population of Italy; most slaves were prisoners of war, or had been kidnapped by pirates raiding the Mediterranean seaports. Owning slaves was a symbol of wealth: some owners had several thousand, others just had two or three. A child of a free man and a slave woman would be free, and many Romans would promise freedom to their slaves after a certain number of years of work. Freedmen would receive (limited) citizenship, and some rose to high positions in imperial times. Slaves could be used for agricultural work, crafts, teaching, mining, or gladiator fights, and could be secretaries, administrators, and so on. In such capacities they worked alongside citizens. The state owned a large number of slaves for public works.

The population of Rome during the first century CE consisted of about 1,000,000 inhabitants, who were mostly supported by the subsidies provided by rich members of the elite, eager to buy votes. *Panem et circenses*, bread and games, were a real phenomenon. The many religious holidays provided plenty of opportunity for handouts. Of all games, the gladiatorial ones were the most famous. The games originated in Etruscan funeral practices, and remained popular in Italy and in its colonies until they were forbidden

in 325 CE. They involved vast expense, and emperors vied with each other in outspending their predecessors: a clear case of conspicuous consumption and influence buying. The contestants often were slaves, prisoners of war, condemned criminals, or citizens who had sold themselves for a fee. The gladiatorial games were held in the Forum during the republic, and later in the Colosseum, which could hold up to 55,000 spectators.

There were many other *ludi* (games) as well: chariot races, for instance, were held in the Circus Maximus, which could contain up to 150,000 spectators and provided permanent tiered seating. Many of the *ludi* were held on religious holidays, whose number increased from about fifty in republican times to close to 180 in the fourth century CE. Gambling and betting on the different teams was common, as were fights among the fans and factions. Other *ludi* are the *ludi scaenici*, or theatrical performances, which began during the mid-fourth century BCE. Initially, performances consisted of mimes and pantomimes, with some musical accompaniment. Later, plays (comedies, tragedies) could be performed anywhere, but they were often connected with temple festivals; temporary seating and stages would be set up. Only in the first century BCE were permanent theaters constructed. *Ludi scaenici* were often paid for by the state and the presiding magistrates. Women and children could attend, but were seated separately from the men. On days of festivals, the courts would be closed, certain agricultural chores were restricted, and some workers would get the day off.

The Roman Family and Roman Religion

The term *familia* could mean "the household": it would include all those who lived in a house, including the slaves. Freed slaves would take the name of the person who had freed them and continued to belong to the *familia*. Roman family structure favored the male line: the *paterfamilias* and all his close bloodline were called *agnati* (sing. *agnatus*). A woman who married into a family became *agnata* as well. She could avoid this fate by spending three nights of the year elsewhere, in which case she continued to be a member of her own father's line, and her property would remain her own. *Cognati* (cognatus) were all those linked by blood; *adfines* were those one was related to by marriage. The *paterfamilias* held power over his entire household and could order the death

Source: © iStockphoto/Luigi Petro.

of his children, forbid marriage, or order divorce. Unless a father released his son from *patria potestas*, the son would remain dependent on his goodwill.

Roman patricians worshipped their male ancestors and had masks representing them hanging in their houses. These masks were worn by actors during important religious events in the family, or during funeral processions en route to the pyre. The lower classes also practiced cremation, the custom in most of Western Europe from approximately the third century BCE until the middle of the second century CE, when the Hellenistic custom of burial took over. The poor often belonged to “funeral clubs” that helped defray the expense. The spirits of the dead were believed to go to the underworld; those refused entrance would wander the earth. Relatives would visit graves and bring offerings of food or small gifts.

The Roman household had its own protective spirits, the *Lares* and *Penates*, who were worshipped in the home. The state had its own set. In general, it can be said that the Roman religious pantheon very closely mirrored the Roman family: an all-powerful father (Jupiter) and a close set of *cognati*. Later, when Greek culture became more influential, the Greek pantheon was “translated” into the Latin one, and characteristics of the gods were adjusted. Once the Middle East was conquered, the emperors found it to their advantage to claim divine descent and demanded to be worshipped the way Eastern potentates were worshipped.

This created problems at home, not so much among the *plebs* as among the other patrician families, and among the adherents of new cults, such as Christianity.

Originally, education of young aristocrats took place at home; both mothers and fathers were involved. But during the late second century BCE Romans began to feel the need for a more thorough education: the conquest of Greece no doubt had much to do with this. Greek teachers and slaves (to teach) were in high demand, and during the first century BCE all

children of patricians (some girls, as well) grew up bilingual. From an early age patrician boys were trained in oratory—after the Greeks arrived, in rhetoric, a more systematic approach to giving speeches and arguing with political opponents. Young men would “finish” their education by studying a few years in Athens or in Alexandria, which was also Greek-speaking. Or, if they wanted, they could study law in Berytus (Beirut), which had a flourishing law school after the first century CE. They could also stay in Rome and attend law school there. With Greek culture came the Greek approach to life and its pleasures, and many conservatives railed against the *graeculi* (the Greeklings). The first century BCE witnessed the growth of Latin literature: much of what is read and studied today was produced during that period or shortly thereafter.

Roman Administration

Rome’s expansion was successful due to its administrative organization. Once it had conquered an enemy, this enemy could become an ally on very generous terms, or else, the city would be razed to the ground. The creation of colonies began in the fourth century BCE, first on Italian soil, later anywhere else. The colonists had their own magistrates and organization, retained their Roman citizenship, and were expected to perform military duties if required. Local

patricians also received privileges and developed loyalty to Rome. During the time of the emperors (beginning ca. 50 BCE) the system was expanded beyond the borders of Italy, and colonies were established as far away as Germany, Spain, Britain, north Africa, and the Middle East.

Of old, the senate played an important part in governing Rome; the senators' power, however, was frequently limited. The origins of the senate are obscure, and it is not certain that it was made up entirely of patricians from the beginning. To be a member one had to own a certain acreage. The number of senators varied over the centuries from 300 to almost a thousand in the mid-first century BCE. The son of a senator would also be a senator, of course, but the highest magistratures went to those who had earned the right to them. High status was conferred, not inherited, and a military career was the surest way to glory and success. Another way was to become an expert in Roman law—especially during the last four centuries of the empire. During republican times, former magistrates became members of the senate for life, and thus controlled most aspects of government, making financial as well as military and religious decisions. Originally the representatives of the *plebs* could only attend the senate by sitting in the vestibule of the senatorial meeting hall; later, they acquired the same privileges as the patrician senators. By the end of the republican period, however, the senate had lost all power.

The republic effectively ended with the rise of Gaius Julius Caesar (100–44 BCE). Although he never took the title of emperor (*Imperator*), he certainly created the model. By means of intrigue, bribery, dubious loans, marriage and other alliances, Caesar, a patrician by birth, managed to gain the trust of the *plebs* and the loyalty of his soldiers. To ensure his succession, Caesar had adopted his great-nephew Octavian, since he had no sons himself. Octavian, although only 18 at the time of Caesar's death, was as gifted in military and political skills as his great-uncle or "father." He took the religious title of Augustus ("consecrated" or "holy") in 27 BCE, thus becoming the *de facto* first emperor, although he claimed to have restored the republic.

The rise of Christianity during the first and second centuries CE created increasingly larger problems for the Roman empire. Originally seen as a sub-sect of the Jewish religion, Christians had been given the

Source: © iStockphoto/Luigi Petro.

same exemptions as the Jews: as monotheists, their religion was not absorbed into the larger Roman religious system, and some autonomy had been given to some Jewish territories. Only in the third century CE was Christian dogma sufficiently established to be seen as a threat to the Roman state; however, by that time the Church had so many members that intolerance was no longer an option.

It is calculated that by the second century CE, the territory ruled by the Empire covered about 2 million square miles, with a population of approximately 55 million. In 293 CE, to facilitate rule and to better control corruption, Diocletian (a usurper himself) split the Roman empire into two: a Roman (western) half, and a Greek half (with its capital in Byzantium).

The third and fourth centuries CE saw increasing attacks from northern tribes, the Goths, Visigoths, Ostrogoths, the Vandals, various Germanic tribes, and in 476 the western Roman Empire was no more. Roman culture (including language and dress) was henceforth transmitted by the Catholic Church and the Pope.

ROWE, JOHN HOWLAND (1918–2004)

John Howland Rowe was a highly recognized scholar of Andean studies with significant contributions in the areas of history, ethnohistory, archaeology, linguistics, and ethnology. Born in Maine, he was educated at Brown University in classics and went on to receive his PhD from Harvard in 1947. He taught and worked to found anthropology programs at universities in Cuzco, Peru and Popayan, Colombia before accepting a position to teach linguistics and archaeology at the University of California, Berkeley. He was promoted to full professor in 1956 and served as an influential department chair from 1963–1967. Before he retired from Berkeley in 1988, he helped to found the departmental library, now one of the largest anthropology collections in the U.S. He was also instrumental in establishing the Kroeber Anthropological Society and the Institute for Andean Studies, the oldest professional society dedicated to the study of Andean culture and archaeology in the U.S. Rowe was the recipient of many honors including several honorary degrees, prestigious fellowships, and Peru's Order of the Sun, their highest civilian honor.

Rowe's scholarly work is considered seminal in several areas. His training in classics prepared Rowe

to deal with both material culture and written documents. His 1946 publication "Inca Culture at the Time of the Spanish Conquest" is an early result of historical research. The piece has remained a standard description of precolonial life in the Andes. Throughout his work on the Inca, he emphasized their highly developed state at the time of European contact and the strong persistence of their cultural patterns into colonial times. This work opened the door for further work on Inca ethnohistory at a time when many scholars claimed that the Inca people had "disappeared."

Rowe's other major contribution was in the area of Andean archaeology. Rowe did not participate in the important Viru Valley Project led by Gordon Willey in 1950. Instead, Rowe turned his attention to the Ica Valley on Peru's southern coast. Working there with students, Rowe developed a chronological sequence that is still used in much of the region today. Rowe's scheme divided Andean prehistory into a series of "periods" of regional development punctuated by "horizons" characterized by the spread of recognizable art styles ("horizon styles") promulgated by state-like or state-level societies (Chavin, Wari/Tiwanaku, and Inca). Rowe's work on chronology emphasized the concept of "style" rather than the "type-variety" concept that took root in the American Southwest.

Rowe's published works include many review articles as well as several publications on Andean culture and language, some of which were equally influential in their subfields. A full bibliography of his scholarly work is available through the George and Mary Foster Anthropology Library at University of California, Berkeley.

RUMBAUGH, D. M. (1929–)

Duane Rumbaugh was born in Iowa in 1929. He earned an MA from Kent State University and a PhD at the University of Colorado where he studied experimental psychology. He has been a leading researcher in the field of comparative psychology and the relationship between intelligence and language since his career began in 1958 at the San Diego Zoo and San Diego State College. His focus has been on primate research (both human and nonhuman), to further the understanding of both the great apes and ourselves. He is well known for the establishment of the LANA (language analogue) Chimp Language Project in 1971. The project, which incorporates the use of symbols and lexigrams, employs Dr. Rumbaugh's innovation of computer-monitored keyboards that examine how primates acquire language. Rumbaugh and his wife, Dr. Sue Savage-Rumbaugh, cofounded Georgia State University's Language Research Center in 1981, which Rumbaugh directed for 20 years. Rumbaugh is currently Regent's Professor Emeritus in GSU's Department of Psychology and Biology. Rumbaugh's interests in understanding our primate cousins and the similarities of how we learn and develop led him to join the Great Ape Trust of Iowa where he coordinates academic and community relations.

Rumbaugh's research draws heavily on the concepts of early cognitive development in both apes and young humans in his studies of language competency. Through his study of children and young adults with learning disabilities, Rumbaugh claims that experience in the early cognitive stages of both human and nonhuman primates is a key component in learning language. Rumbaugh's research shows that both human and nonhuman primate brains look for patterns, craving to structure their environments. From these patterns emerge what Rumbaugh terms "emergent" behavior, or behavior that does not follow any set pattern. Emergent behavior is not predictable or set by any type of reinforcement. Rumbaugh has said that "primates (both human and non) have the ability to manifest intelligence because they compute their experience relative to the here and now, and try to optimize, to do things efficiently, which means to do things in creative ways."

RUSSELL, DALE ALLEN (1937–)

Dale A. Russell is a vertebrate paleontologist whose contribution to anthropology is limited to a 1981 paper published with model-maker Ron Séguin proposing a hypothetical hominid-like "dinosauroid" evolutionary endpoint for troodontid dinosaurs. Russell and Séguin postulated that if non-avian dinosaurs had not become extinct, they could have evolved, as did primates, toward a hominid form that is an evolutionary ideal for intelligent beings.

Russell received his BA in general science from the University of Oregon, Eugene in 1958, his master's in paleontology from the University of California, Berkeley in 1960, and his PhD in geology from Columbia University in 1964. He conducted post-doctoral research at Yale University under John Ostrom before becoming curator of vertebrates at the Canadian Museum of Nature in Ottawa, where he spent most of his career. It was during his time in Canada that he described the troodontid dinosaur *Stenonychosaurus*, which served as the inspiration for his controversial "dinosauroid" paper published in 1981. During his career, he has participated in field-work in Mongolia and has described a number of dinosaurs from around the world. He is also noted for his 1971 paper with physicist Wallace Tucker suggesting that a supernova led to the extinction of the dinosaurs, which, while never widely accepted, was the first extraterrestrial hypothesis for dinosaur extinction. He is further noted for the description of a fossilized heart in a specimen of the dinosaur *Thescelosaurus* in 2000, which is now considered unlikely. He is currently the Senior Curator of Paleontology at the North Carolina Museum of

Natural Sciences and a visiting professor at North Carolina State University.

RUSSIA AND EVOLUTION

Russia produced a number of notable evolutionists who contributed to research and theory in natural history, biology, and anthropology. Russian intellectuals widely accepted Charles Darwin's *On the Origin of Species* (published in Russian translation in 1860) and the evolutionary force of natural selection, but reaction to it was shaped by various political leanings and ideological goals. Russian progressives and anarchists were generally less predisposed to the theory as they felt it reflected the bourgeois intellectual tradition in Britain. Some conservatives, however, were proactive Darwinists (for example, K. A. Timiriazev, for whom a present-day State Biological Museum and Agricultural Academy in Moscow are named). Social transformation in Russia intensified with the emancipation of the serfs in 1861, and many descendants of nobility, military, and urban classes pursued careers in the sciences. There was a small but engaged and prepared audience for evolutionary theory in Russia in the 19th century.

Indeed, many Russian evolutionists took issue with one particular facet of Darwinian evolutionary theory while maintaining their general acceptance of the theory. This issue was Darwin's use of the 18th century Malthusian concept of the "struggle for existence" that was attributed to British competitive individualism and popular acceptance of Malthus. The struggle for existence stood for overpopulation and intraspecific competition as forces driving Darwinian selection. Rather, Russian intellectuals felt that competition was specific to particular ecological conditions. In Russia, wide expanses of the natural world were sparsely populated, especially in Siberia. Naturalists focused on cooperation and variation within species as evidence counter to the struggle-for-existence assumption. Human population pressure was not as great in Russia as Britain, and the communal lifestyle of the Russian peasantry was an important

form of social organization for 90% of the population. Russia was a net exporter of agricultural products during the 19th century. Russia had a small middle class and exhibited little social competition; society was markedly hierarchical, but the communitarian values of the Russian majority were an ideal to be envied in some Western academic circles (for example, August von Haxthausen in *Studies on the Interior of Russia*, 1850).

Karl Kessler, one of Russia's leading 19th-century naturalists and ichthyologists, defended Darwinian selection theory in publications in the 1860s and 1870s, but in 1879, Kessler gave a speech "On the Law of Mutual Aid" to the St. Petersburg Society of Naturalists challenging the primary role of the struggle for existence. According to the law of mutual aid, fish and all animals, including humans, were governed primarily by parental feeling and care of progeny as instincts driving nourishment and reproduction. Alliances among former enemies evidenced the increasing material and moral benefits of mutual aid. Kessler died in 1881 before publishing his theory of mutual aid, but a number of Russian scholars picked up Kessler's idea and developed it, including A. F. Brandt in *Symbiosis and Mutual Aid* (1896) and Prince Petr Kropotkin in *Mutual Aid: A Factor in Evolution* (1902). The concept of *vzaimnopolomosh*, or mutual aid, was common sense in Russian society, a factor which may have led to the success of the 1904 Russian translation of Kropotkin's book from the original English. Mutual aid was the strong force driving natural selection in 19th-century Russian evolutionary theory.

From Mutual Aid to Reciprocity

Prince Petr Alekseevich Kropotkin (1842–1921) began five years of military service in Siberia when he was 19 and uncertain in his career plans. He turned his attention to naturalistic observations, and as Darwin's observations on the *Beagle* 30 years earlier informed his view on evolution, Kropotkin's travels through Siberia were an avowed influence on his theory. The severity of climate in Siberia, destruction due to natural calamity, and a lack of intraspecific conflict led Kropotkin to emphasize cooperation as the creative factor in evolution. Kropotkin perceived environmental threat and the paucity of life, rather than overpopulation. He observed migrations

of fallow deer on the Amur, great gatherings of birds in the Usuri, and herds of semi-wild horses and cattle in Transbaikalia, and he saw these animals struggling together for sustenance, not against one another. Kropotkin felt that intraspecific competition could not lead to “progressive evolution,” and following Kessler, argued that mutual aid was far more important than mutual struggle in evolution. Similarly, Kropotkin was critical of the Hobbesian view of each against all as the law of life for primitive man.

Kropotkin made a deduction about the origin of human sociality following the law of mutual aid. Kropotkin argued that sociality originated in colonies where mutual aid institutions—for example, communal life among Australian Aborigines and the Bushmen’s fondness for sharing—began, and that the family was an institution of recent invention. In the course of history, mutual aid institutions were invaded by what Kropotkin termed “parasitic growths,” in which individuals rebelled in two ways. Those building higher-level institutions, or commonwealths, followed one path away from mutual aid. Those who were more self-centered and worked to build their own wealth followed the second. The tragedy of history, as Kropotkin put it, was a “three-cornered contest” in which those living in mutual aid became a hindrance to progress. As societies began to lose their primitive character, Kropotkin argued that more gentle institutions, such as clans and families, began to develop. The family was a late product of human evolution for Kropotkin, and sociality had its origins in communal life. Similarly, the role of family in human life history evolution is currently questioned among anthropologists.

Russian ideas about mutual aid and its role in evolution occurred almost a century before analogous ideas made their way into anthropology from biology and game theory. Today, the evolution of cooperation is widely appreciated in terms of reciprocal altruism and strategies such as “tit for tat” cooperation. Kropotkin realized the origin of such strategies was an important issue, but he reserved speculation for future “ulterior” studies.

Twentieth-Century Russian Evolutionism

At the turn of the 20th century, social upheaval in Russia took evolutionary theory on a turn toward the Marxist-Leninist theory. Following crude group selection arguments, Vladimir Il'ich Lenin (1870–1924) and his followers argued that peasants and indigenous people were entering into a stage of capitalism from the feudal or the primitive social stages of evolution. Communism was to be the ultimate evolutionary stage with no formal state. Studies of Russia’s peasant commune, or *mir*, aiming at producing models alternative to unilineal Marxist-Leninist theory, influenced anthropology through the research of populist agricultural economist A. V. Chayanov and others. Chayanov’s data provided important comparisons for Marshall Sahlins’ concept of the domestic mode of production. Chayanov had evidence that the Russian peasant’s willingness to drudgery varied with the life

cycle of the household, and this created cycles of socioeconomic differentiation. Chayanov proposed a path of development that was an extension of the peasant *mir*. However, as Lenin had already surmised that class exploitation was the cause of differentiation, Chayanov's data and suggestions were considered counterrevolutionary. Chayanov's theory directly challenged the assumptions of those promoting rapid modernization and unilineal thinking about social change, and he lost his life in the purges, as did many academics at that time.

Lenin's followers devastated the Russian countryside during the Bolshevik Revolution and resulting civil war, and then, the New Economic Policy (1921–1928) allowed a short period of entrepreneurial activity, intended to jumpstart the Russian Soviet economy. What followed after Lenin's death—Stalin's policies of collectivization and amalgamation of peasant communes into politically directed workshops (for example, *artel*), collective farms (*kolkhozy*), and then state farms (*sovkhozy*)—was draconian and guided by the goal of building socialism. The suffering of the Russian population and deaths estimated in the millions during collectivization and the purges was a result of unilineal evolutionary social engineering.

Soviet evolutionism and the war on primitive communism was particularly harsh for certain ethnic groups, such as the Volga Germans, who were uprooted and sent *en masse* to exile in Siberia, and the indigenous peoples of Siberia. The indigenous Siberians became targets for Soviet missionaries because many native Siberians were illiterate; they lived under the common law, but the Tsar had named hereditary kings (*kniiazki*) to collect tribute. There were successful herdsmen who owned thousands of animals while the poor owned less than 50. There were middle-men mercantilists and practitioners of shamanism. Under Marxist-Leninist ideology, mutual aid and other institutions of primitive communism were hindrances to progress. Many Siberians who had resisted Soviet power in the 1920s and early 1930s, large herd owners and shamans in particular, were arrested and executed in the late 1930s. Soviet evolutionism was teleological, dogmatic, ethnocentric, and tragic.

In contrast, 19th-century Russian evolutionism has its modern descendants in anthropology. For example, Kropotkin's emphasis on mutual aid among hunter-gatherers is reinterpreted in Alan Barnard's

“foraging mode of thought.” Russian evolutionism has also informed anthropological studies of economics in small-scale societies, peasants, utopian communes, and societal change. The role of Russian scholars in the development of evolutionary theory and its interpretation in anthropology should not be overlooked.

Russian plant geneticist Nikolai Ivanovich Vavilov (1887–1943) is another evolutionary biologist who suffered under Soviet politics. Vavilov gathered a vast collection of plant seeds and conceived the theory that domesticates originate in regions where the species in question and its parasites showed maximum variation. He eventually proposed seven main centers of origin for plant domestication and multiple smaller centers, based on modern crop and wild plant phenotypes and genotypes. Vavilov also proposed the idea of primary and secondary domesticates. Secondary domesticates are weeds that grow along with primary domesticates that are watered, inadvertently harvested, and eventually domesticated. He linked his theory of plant domestication to the problem of animal domestication and the development of early civilizations. In 1940, Vavilov was repressed as a promoter of “bourgeois pseudoscience” by the head of the Institute of Genetics of the Soviet Academy of Sciences, Trofim Lysenko. Vavilov died in prison in 1943. His work is still cited by archaeologists studying domestication processes.

STATE DARWIN MUSEUM, MOSCOW, RUSSIA

Initially founded in 1907 by Alexander Kots (1880–1964), a professor at the Moscow Higher Women's College, the State Darwin Museum has had a complex and difficult history. The plans to expand the museum were constantly pushed aside and then resumed for more than 80 years. The museum is now one of the biggest in the world in the field of natural history, detailing the beginning, growth, and diversity of life on the Earth; the evolution of animal behavior and the distribution of animals on the planet; and the origin of humanity and the history of its relationship with nature. It also holds the largest collection of aberrant mammals and birds, which has a unique scientific interest, consisting of 800 mounts with the rarest aberrations. In addition to regular specimens, in concert with the beliefs of its founder, the State Darwin Museum features extensive use of wildlife art. Kots believed that wildlife art could stimulate the public interest in biological diversity.

The relationship between the museum and the different regimes that governed Russia in the

20th century were not always easy. The location given to the museum in 1913, the building of the Higher Women's College, soon proved to be too limited for the scope of the collections. Although the Soviet government passed a decree for the building of a new and larger museum as far back as 1926, the founder did not live long enough to witness it. Four years before his death, Kots, whose entire life was committed to the establishment of the museum, was forced to say that his expectations could not be fulfilled because of the sad conditions of Russian society. When the building of the Women's College, which had been renamed the Lenin Pedagogical Institute in the meantime, became unsafe in the 1980s, the museum was even closed to the public. The construction of the new museum had started in 1974 but was only completed 20 years later, and the permanent exhibition was not opened until 1997, the 90th anniversary of the museum. Yet when the new museum was finally established, its building was already too small for its fast-growing activities and events, and in 1994, a new decree was issued granting the construction of an additional building.

— Luca Prono

SAGAN, CARL (1934–1996)

Jewish-American astronomer and physicist Carl Sagan was known for both his popularizing of science and addressing social issues with an evolutionary awareness. Born in Brooklyn, New York, Carl Sagan was one of two children born to Sam Sagan and Rachel (Gruber) Sagan. Considered to be an intelligent and inquisitive child, his interest in science began at an early age due to the ever-growing popularity of science fiction as well as advancements in technology. Graduated from Rahway High School (1951), Sagan entered the “Hutchins Program” at the University of Chicago, where he received his BA in 1954 and 1955 (general and physics) and MA (physics) in 1956. Sagan continued his education at the University of California, Berkeley and received a PhD (astronomy/astrophysics) in 1960.

Considered an inspirational teacher, Sagan taught at both Harvard University (1962–1968) and Cornell University where he was director of the Laboratory of Planetary Studies. Yet his major contributions were in research and writing, such as his insights into atmospheric conditions on the planet Venus and planetary conditions on Mars in relation to the possibility of extraterrestrial evolution elsewhere in the universe. Working on various government projects, he was well known for his contributions to the *Galileo* and *Pioneer X* and interpretative results of the *Mariner* unmanned space probes. Further inquiry into extraterrestrial life continued by SETI (originally Project OZMA) established Sagan as a prominent scientific figure and reaffirmed his own speculation into the existence and duration of extraterrestrial life. However, it was Sagan’s ability to convey technical scientific information and stimulate the

public’s imagination that made him famous. Sagan was best known for his PBS series *Cosmos* (1980) and his novel *Contact* (1985), which was later adapted for film by Robert Zemeckis (1997). Sagan also received many awards and medals for his academic, public, and literary contributions.

Sagan’s academic achievements and theoretical development were directly or indirectly influenced by H. J. Muller, Harold Clayton Urey, Stanley Miller, Joshua Lederberg, Gerald Kuiper, and Jim Pollack. His theoretical orientation was driven by hopeful speculation about the evolution of extraterrestrial life. To these ends, Sagan had directed his scientific inquiries toward the theoretical precursors of life on this planet and other planets in the universe. Consequently, atmospheric and general conditions became a point of scientific speculation. Due to proximity, and perhaps influenced by the romanticism of science fiction, the planets Venus and Mars became targets in the quest for planetary knowledge and possible confirmation of extraterrestrial life. Drawing upon the popularized “greenhouse effect” on our planet, Sagan applied this principle to the conditions on Venus. According to Sagan, Venus’s greenhouse effect was due to a combination of carbon dioxide and water vapor (Sagan’s addition) that would serve to retain inferred radiation. Though high surface temperatures were speculated, Sagan speculated that Venus’s planetary rotation could possibly hold temperatures to a point that may support life, for example, similar to life found in extreme temperatures at thermal vents. The information sent by *Mariner II* confirmed Sagan’s belief that intense radiation contributed to Venus’s temperature (greenhouse effect). However, Venus’s surface temperature was greater than expected; consequently, it appears impossible for Venus to support life.

Source: © Bettmann/CORBIS.

Turning to the planet Mars, Sagan speculated that life, albeit microbial, may exist. However, the preliminary photos taken by *Mariner IV* did not expose any overt expressions of life. He then speculated on two key Martian features: the “canals” and the “wave of darkening” that are observable. As a plausible explanation, Sagan hypothesized two points concerning these features: the “canals” were a product of plate tectonics and the “wave of darkening” is a product of raging turbulent dust storms. Although the explanation for the appearance of “canals” was proven false, the explanation of dust storms retained its viability. However, as science advanced, the possibility of simple or advanced extraterrestrial life on Mars was negated by both *Viking* and more recent expeditions.

Influenced by both scientific method and Darwinian evolution, Sagan rejected religious or traditional cosmologies in favor of a rational and scientific explanation. In this critical process, he fought and exposed the pseudoscience that is often promoted and accepted without critical analysis. From the annals of theoretical space exploration and the duration of technological life in the universe (known as the “value L”), Sagan turned his attention to problems that face our species on this planet. He opposed militarism and the nuclear buildup of the Cold War, mostly contributing to the debates on SDI and the reality behind a nuclear winter. Promoting peace, democracy, and education, Sagan continued to endorse an optimistic view in an otherwise nihilistic reality of planetary extinction.

Implementing whimsical and catchy phrases like the *Baloney Detection Kit*, Sagan encouraged readers to apply skepticism and logic in the evaluation of any expressed ideas—religious, political, and scientific. As a secular humanist, evolutionist, and materialist, Sagan knew the perils that ultimately face an individual. Even during his life-ending battle with complications from myelodysplasia, Sagan continued to enlighten and promote the peaceful unity of our species. Perhaps it was his understanding of the true nature and implications of evolution in the cosmos that

contributed to his relentless and productive quest for extraterrestrial life.

SAHARA ANTHROPOLOGY

Late Stone Age North and West Africa have been stereotyped as a monolithic culture in two hypotheses: the African Aqualithic and the Neolithique de Tradition Soudanis. Lithic diversity was ignored in favor of a broad-based cultural tradition defined by remains from aquatic activities and by the supposed observance of wavy-line and dotted wavy-line pottery. However, a recent reanalysis of Saharan pottery concluded that wavy-line pottery constitutes a pottery mode-tradition rather than a horizon style, thus restricting the value and applicability of the Khartoum Horizon Style to the dotted wavy-line component only for the Sahara-Sahel Belt. The dotted wavy-line

motifs frequently appear with other motifs on the sherds, reducing their diagnostic value and highlighting the cultural variability of the region in the early Holocene. Furthermore, some of these motifs are misidentified.

In addition, the McIntoshes, influenced by the ferrocenic tenets of *Technology, Tradition and the State in Africa*, dismissed early pastoralists as the progenitors of social complexity and downplayed the importance of Late Stone Age Dhar Tichitt.

By contrast, MacDonald approached the issue by using polished stone rings and hachettes (defined as small axes under six centimeters) to hypothesize a tandem spread of the items subsequent to the initial adoption of pastoralism across the Sahara and their use as mediums of exchange. His model postulates that the spread was complete throughout the Sahara-Sahel by 1800 BC. This chronologically distributed pattern, stressing long-distance mediums of exchange with cattle serving as their repositories of wealth, is taken as indicative of incipient social complexity arising ca. 4000 BC. with transitory leadership positions; these transitory peaks eventually took hold and developed into complex, hierarchical societies such as seen at Dhar Tichitt and Kerma.

MacDonald's hypothesis has been incorporated by Andrew Smith into a model of population movement claimed to be depicted in the rock art of the Tassili. Smith relates the appearance of Proto-Berbers, represented by the white-face rock art style, around 3500 BC with the black-face style of preexisting populations, showing ideological similarities to modern Fulani cultural practices. Following the results of Paris's excavations of burials and settlements in the Aïr Mountains of Niger, and his tenuous conclusion of a migratory flow of Proto-Berbers of unknown origin bringing with them tumuli, Smith brackets these events as a package. The platform cairn, making its earliest appearance ca. 3800 BC in the Central Sahara, is regarded in the model as

the earliest form introduced by the Proto-Berbers, who Smith postulates originated in Northeast Africa.

Northeast Africa is the location for the claimed earliest expression of pastoral social complexity. The postulated degree of control over labor and the expression of ritual activity by Nabta Playa's Late Neolithic (ca. 5000 BC) inhabitants for the construction of the cattle tumuli and stone structures has been heralded as the start of social complexity in the Egyptian Western Desert, which subsequently influenced the ideology of the Predynastic Nile Valley inhabitants.

These competing hypotheses share a common thread in recognizing that socioeconomic strategies are manifestations of behavioral adaptations whereby knowledge and culture are transmitted through social learning. They differ in timing when the accumulated repertoire was materially expressed in a wide diversity of situations through socially mediated responses to internal or external stimuli. Social diversity serves as a warning against simplistic, linear models. It highlights the importance of developing an explanatory framework for investigating regional socioeconomic networks against the backdrop of differential resource access, environmental stimuli, variable cultural norms, and socio-ideological evolution.

New data, from the excavated Saharan tumuli in the 1990s and early 21st century, are helping to redefine the previously held tenets by demonstrating meaningful occurrences of symbols empowering

Source: © iStockphoto/Eileen Morris.

socio-ideological settings in socially transmitted patterns. This social reproduction of culture needs to be engaged with and defined anthropologically to a greater degree than is currently done by Saharan archaeologists. The construction of the Saharan tumuli was probably the outcome of the interpopulation integration outlined earlier, under variable degrees of resource abundance. This integration was likely to have been preceded by warfare in the Libyan Sahara, evidenced in Late Pastoral (3900–1800 BC) rock art from the Acacus, and the emerging dominance of prominent individuals in Messak Settafet rock art. Yet while rightly recognizing the relationship feedback between landscape, structure, and society, an important avenue of this investigation has been the role the act and consequence of building the tumuli had on the reproductive capabilities of the society. Designating and linking landscape systems and exchange goes some way toward explaining how social complexity arose and became institutionalized.

The production of these tumuli would also have involved redistribution of resources by the elite at the accompanying ritual celebrations. The set of shared values, wherein the social value of a clan or lineage was affirmed, applied to individuals along horizontal sections of society. The social access to status burial was thus widened but remained elitist, and distinct disposal areas were formed in Wadi Tanezzuft. These serve as cultural markers of vertical differentiation, or incipient complex social hierarchy, with a strong trend toward ethnic fragmentation that increased ca. 1800–810 BC in Wadi Tanezzuft with formalized burial sites and ceremonial centers.

There existed in the Late Neolithic increasing ethnic fragmentation and pooling of economic wealth (in the form of ovicaprids or cattle, depending on the region) in the hands of an emerging lineage elite and formalized through the acquisition and control of prestige trade items with regionalized mediums of exchange. Contra the McIntoshes, the pastoral burials were not constant. They vary in time and space, and the material culture demonstrates socially transmitted patterns of culture through cumulative inheritance systems. The deposition of goods within the tumuli show that the descendants were wealthy and powerful enough to dispose of them.

Cultural structures, imbued with power symbolism, were visible symbols of social organizational principles with wealth accumulation partly substituting for abstract symbols. The rise of the political ideology

of domination and enculturation, with its thoughts and rules, lies behind the regulation of behavior and the instigation of principles of descent, selective material redistribution for prestige, and labor divisions. These early manifestations of social complexity and hierarchy separated ritual and political influences and were the basis for the later early Sahara, West African and Nubian states.

SAHELANTHROPUS TCHADENSIS

Sahelanthropus tchadensis is an extinct hominin discovered in Chad in 2001–2002. The fossils were discovered by Michel Brunet and colleagues, who are part of the Mission Paléanthropologique Franco-Tchadienne (MPFT).

The species name literally means Sahel-man from Chad; Sahel is the name of the region where the fossils were found. Brunet and colleagues have nicknamed the fossil skull Toumaï (or Toumai), which means “hope of life” in the local Goran language.

The holotype (the specimen that illustrates the characters of the species) includes a nearly complete cranium and the other fossils include parts of two mandibles and some isolated teeth.

At the time of this writing, the fossils are still being analyzed; however, it is clearly a very important specimen for a number of reasons. First, at 6–7 million years old, the age of the specimen places it around the time of the common ancestor of humans and chimpanzees. The discoverers claim that it represents the

oldest hominin discovered thus far—one very close to the root of the human family tree.

Second, if the Toumai fossils represent the oldest hominins, their discovery 2,700 km west of the Rift Valley in East Africa brings into question the long-standing theory that East Africa was the birthplace of hominins. This fossil, together with other early fossil hominins like *Orrorin* and *Ardipithecus*, suggests that early hominins in the late Miocene were geographically more widespread than previously thought. In addition, if Toumai proves to be bipedal, walking upright like humans, the mosaic environment associated with the fossils may also suggest that this key adaptation evolved before hominins moved onto the savanna.

Finally, the remarkably complete skull presents a unique combination of ape-like and human-like characters that make it particularly noteworthy. Although the brain is the size of a chimpanzee's, the face is more human looking than hominins half its age. The human-like characters that link this specimen to other hominins include the small upper canine teeth, which are worn at the tips, and the intermediate thickness of the enamel in the premolars and molars. Aspects of the skull also align it with other, more recent, hominins. These include the size and shape of the foramen magnum (the hole in the base of the skull for the spinal cord) and a relatively flat face.

The relationship of Toumai to other fossil hominins and modern humans is currently unknown. It may represent a species that was a sister group of other hominins, or it could be part of the human lineage. There is even some controversy regarding whether or not the fossil actually represents a hominin. Perhaps the chief significance of this fossil is the finding of unsuspected diversity of early hominins. This suggests that there were likely many “experiments” with becoming human, some of which were more successful than others.

SAHLINS, MARSHALL D. (1930–)

Marshall D. Sahlins, a prominent and highly esteemed anthropologist and ethnographer, is recognized internationally for his theory of the historicity and pervasiveness of culture in everyday life and the process of cultural change.

Born and raised in Chicago, Illinois, Sahlins completed his undergraduate work at the University of Michigan and his graduate work at the University of Michigan and Columbia University. He served on the faculty of both universities, and since 1973 has been Charles F. Grey Distinguished Service professor of anthropology at the University of Chicago, while lecturing at Cornell University and throughout North America, Europe, and Asia. He has been a member of the American Academy of Arts and Sciences since 1976.

Sahlins gained international attention and excited anthropological debates as a result of his theory about the history of European contact in Polynesia and his work with indigenous peoples of the Hawaiian Islands. He has also conducted ethnohistorical field research in Turkey.

Sahlins's assertion that culture will always exist, albeit transformed, since it has historically differentiated people through segregation, domination, and repression, has stirred debate about the consequences of globalization for distinctive cultures. He maintains that a process of cultural recuperation will occur in which culture will live in new forms, emerging from cultural resistance and new patterns of human life. As he puts it, “homogeneity and heterogeneity, modernity and tradition are no longer opposed terms.”

Throughout his works *Moala: Culture and Nature on a Fijian Island* (1962) and *Evolution and Culture* (with Elman R. Service, 1960) and in his lectures, Sahlins describes collective interpretations of culture and its enduring nature, maintaining that culture will always exist as it adapts and transforms. His argument against the cultural diffusion position—that Western civilization has invaded and destroyed the cultures of indigenous populations—has gained increasing support from cultural anthropologists. Sahlins argues that cultural resistance modified Western influence and that Western scholars may not understand non-Western peoples and their cultures, which are resisting and changing globalization “through . . . new patterns of human life.” His theory

of cultural change helps explain the dynamics of adaptation and conflict during globalization. Sahlins's other books, *Social Stratification in Polynesia* (1958) and *Stone Age Economics* (1972), contain elaborations of his theory of cultural change based on his very extensive ethnohistorical research on social stratification, decision making, and customs by analyzing material flow and social relations, types of reciprocities, and the relationships between reciprocity and kinship, wealth, food, friendship, alliances, peace-making, and marital alliance. Sahlins provides strong support and verification for his theory.

The significance of Sahlins's theory of cultural change lies in its influence on contemporary anthropologists to conduct ethnographic field research in small-scale cultures with a perspective of the changing forms and dimensions of traditional cultures, resulting in a basic theoretical component of cultural change and social change curricula and ethnographic methodologies.

In summary, Sahlins has championed understanding cultural differences by focusing on collective interpretations of culture. By understanding the patterns of non-Western peoples, he maintains that Western anthropologists can research cultural change but may not be able to understand non-Western mentalities.

Sambungmachan is an archaeological site in Central Java, Indonesia, from which three crania have been recovered. The earliest finds consist of a nearly

complete *Homo erectus* (Sm 1) cranium missing the face and part of the base, the central portion of a *Homo erectus* tibia, and numerous remains of Late Pleistocene mammals. The date of the skullcap and tibia fragment has proved impossible to determine. Based on its mineral content, it probably dates to the Late Pleistocene. The cranium is probably male, and has a cranial capacity of 1,100 cc. The skull is important because it shows a mixture of *Homo erectus* and *Homo sapiens* characteristics, such as a thick cranial bone, pronounced brow ridges, high forehead, and rounded brain case, that link it to the *Homo sapiens* of the Ngandong site and earlier *Homo erectus* specimens from the site of Sangiran. The tibia fragment was found years after the cranium. It is similar in morphology to other *Homo erectus* specimens, such as Kabwe in Africa and those found at Zhoukoudian in China.

Recently, a new cranium (Sm 3) was recovered that has been attributed to the Sambungmachan site based on its overall morphology. It was found among a collection of curiosities sold by an antiques dealer in Jakarta to a New York City antique dealer. The owner of the store took it to Eric Delson, a physical anthropologist at the American Museum of Natural History. Delson identified the skull as *Homo erectus* and similar in morphology to the known specimen from Sambungmachan (Sm 1). The probably male cranium, like the original Sambungmachan specimen, shows a mixture of *Homo erectus* and *Homo sapiens* traits. However, unlike Sm 1, the cranial capacity of Sm 3, is only 875 cc. Because it was found out of context, the age of the skull cannot be determined except in broad terms and is approximately 100,000 to 1.5 million years old.

In 2002, an additional cranium was found at Sambungmachan (Sm 4) by a local farmer while collecting sand. The skull is that of a middle-aged *Homo erectus* who suffered and recovered from two head wounds. Unlike the other two skull caps found at Sambungmachan, the morphology of the new cranium is similar to early *Homo erectus* from the sites of Trinil and Sangiran, which date from 1.2 to 1.8 million years ago.

SAMBURU

The Samburu are, traditionally, a pastoral society found in central northern Kenya. They probably number between 100,000 and 200,000. The Samburu are closely related to the Maasai, they speak a dialect of Maa, and they share a common history with the Maasai and have a similar social organization. Both are polygamous and have age-sets; Spencer identified six ascending levels of a segmentary descent system: the lineage group, hair-sharing group, sub-clan, clan, phratry, and moiety.

There are, however, important differences from the Maasai. The Samburu have been less affected by colonial land alienations. Indeed, the Leroghi Plateau, which they now occupy, was once cleared of Maasai for colonial occupation but incorporated into the White Highlands. The Samburu have also, relatively recently, adopted camel pastoralism. Camels are expensive stock requiring very different treatment and herding from cattle. Their adoption has been eased by the harsher and drier conditions in the lands where the Samburu live.

The Samburu are close allies with the Rendille and Ariaal, both smaller pastoral groups who live in the same region. In common with other ethnic groups in the region, they intermarry and form diverse alliances

of trade, friendship, and cooperation. In times of extreme hardship, such as the rinderpest epidemic of the late 1880s, the surviving Samburu sought refuge among their neighbors.

In common with other pastoralists in this region, Samburu homes consist of an inner kraal around which huts are built by adult married women, and the whole is fenced with bushes. Several families can share one compound, although stock may be segregated and each man's herd may leave by a different gate. Stock are valuable for all sorts of purposes; the favored food, however, is milk, which women collect in the morning and evening from cattle allocated to them on marriage. It is not typical for wives to share each other's stock. Indeed, it is quite possible for one wife's herd to prosper and another to fail. Each has to contend with her fate. Although wives milk and tend animals and allot them to their children, sale of stock is a male prerogative, leading to problems of impoverishment for families with profligate or alcoholic fathers and intense family debates over which animal is sold.

In recent years, the Samburu have experienced the diverse problems with their governments that afflict most pastoral populations. These include the pressures to settle and adopt sedentary livelihoods amid allegations of desertification, the requirement to modernize, and, allegedly, state-sponsored cattle raiding. Recently they have also lost land to conservation interests with the establishment and enforcement of protected areas. They, like the Maasai, have generally resisted pressure to change their dress, but livelihoods are diverse. In common with other groups, Samburu

politics are responding to the new opportunities presented by nongovernmental organizations.

Samoa is a chain of nine islands in the South Pacific located about 14 degrees south of the equator and divided into two political entities—the U.S. Territory of American Samoa and the neighboring independent

country of Samoa (formerly Western Samoa until 1997). The Samoan archipelago is primarily volcanic and comprises of three major islands, Savai'i, Upolu, and Tutuila, and several smaller ones, including Olosenga, Ofu, Ta'u (the latter of which form the Manu'a group), and two coral atolls, Swains and Rose. The Samoan islands were formed by volcanic activity and are essentially mountains and ridges of erupted rock sitting on the Pacific Plate. Although no volcanic eruptions have been historically recorded in American Samoa, eruptions have occurred on the island of Savai'i as recently as the early 1900s.

Archaeological evidence suggests that the Samoan islands, as well as others, including Vanuatu, the Loyalty Islands, New Caledonia, Fiji, and Tonga, were first colonized by Austronesian speakers from Melanesia. These peoples were known as Lapita, makers of a distinctive dentate-design pottery who traveled east around 1300 BC as part of a major diaspora into Remote Oceania. Numerous radiocarbon dates from archaeological sites such as To'aga on Ofu and 'Aoa on Tutuila demonstrate that Samoa and the rest of these island groups were settled by Lapita no later than 900 BC.

These first settlers were horticulturalists and skilled ocean navigators who brought with them plants and animals such as taro, pigs, dogs, and chickens. The quick dispersal of Austronesian speakers

Source: © iStockphoto/Brandon Upper.

from Southeast Asia into parts of Melanesia and eventually Polynesia is attributed to their invention of the outrigger sailing canoe and mastery of various navigational techniques such as a compass using the stars.

Samoa and Tonga appear to have been the jumping-off point for Polynesian dispersal eastwards after about 500 BC. Ancestral Polynesian culture and Proto Polynesian language developed in this region between ca. 900 and 500 BC directly out of the founding Lapita cultural complex.

Archaeologically, Samoa is probably best known for its distinctive star mounds—massive rock platforms with radiating arms built by the ancient Samoans for cultural and sporting events—and stone adzes made from basalt. Large quantities of basalt debris have been found in village sites such as Maloata and Tulauta, and large basalt boulders with smooth dish-shaped concave areas, sometimes with grooves for sharpening the bits, have been found in streams and along the coast. The excellent quality of the basalt found in Tutuila made it especially attractive for ancient Polynesian tool makers. Chemical analysis of the adzes indicate that Samoan stone was highly sought after and traded or transported to islands hundreds of miles away.

The first recorded European contact of Samoa occurred in 1722, when Dutch navigator Jacob Roggeveen sighted several of the islands. He was followed by French explorers Louis-Antoine de Bougainville in 1768 and Jean-François de La Pèrouse in 1787. A monument in Aasu, Massacre Bay, is dedicated to the 12 members of La Pèrouse's crew who were killed there. The first European Christian missionary, Englishman John Williams of the London Missionary Society (LMS), arrived in 1830. He succeeded in converting many Samoans to Christianity, and his followers had a profound impact on Samoans and their cultural lifeways.

Of the four major geographical areas where fossil hominids are found, Southeast Asia is the least understood. Except for some isolated teeth, the only fossil hominid remains in Southeast Asia are from sites near the Ngandong (Solo) River of central Java, Indonesia. Of fossils sites in central Java, Sangiran is the most important. The villages in Sangiran are famous among paleoanthropologists because they lie on sedimentary layers rich in the remains of *Homo erectus* and other extinct plants and animals. Fossils from the dated volcanic levels of Sangiran indicate that *Homo erectus* lived in the Sangiran area for almost two million years.

Approximately 150,000 years ago, volcanic pressure pushed the Sangiran area into a volcanic dome. This dome has been eroded by natural forces (rivers, rain, and humidity) into the depression that exists today. Currently, the Javan Plio-Pleistocene is subdivided into four major geological formations: the Kalibeng (Upper Pliocene), the Pucangan (Lower Pleistocene), the Kabuh (Middle Pleistocene), and the Notopuro (Upper Pleistocene). The Sangiran Dome deposits exceed 300 meters in thickness and encompass all four formations. With the exception of the Kalibeng, these deposits have yielded at least 100 fossils and numerous teeth of *Homo erectus* and *Homo meganthropus*.

The importance of the site of Sangiran was determined by paleoanthropologist Ralph von Koenigswald in the 1930s. The site of Sangiran is filled with cereal grains grown by the local inhabitants. In the process of farming and seasonal monsoon rains, the deposits of Sangiran continue to be eroded, yielding the remains of *Homo erectus* and dozens of other mammals such as buffalo, turtle, crocodile, hippopotamus, rhinoceros, and elephants. These farmers have an intimate knowledge of where fossils can be found. Von Koenigswald quickly recognized the farmers' knowledge and offered payment for fossil humans.

At first, Von Koenigswald was paying the farmers for each fragment that they brought to him. He changed his policy when he discovered that the farmers were breaking large fragments into several pieces to get more money. In the early 1960s, an Indonesian geologist/paleoanthropologist, S. Sartono, continued the work of Von Koenigswald and taught the local people how to identify human fossils. Nearly all of the important specimens from Sangiran have been found by local farmers who removed them from their original locations and brought them to Sartono. Because they were not found in a controlled archaeological excavation, the dates of the important specimens remain problematic. In 1996, the importance of the Sangiran site was recognized and protected as a World Heritage Location by UNESCO.

SAPIR, EDWARD (1884–1939)

Edward Sapir was an American anthropologist and professionally trained linguist. He was one of the founders of the science of linguistic anthropology. He made significant contributions to general linguistic theory, Amerindian linguistics, and Indo-European linguistics. Sapir also made substantial contributions to cultural psychology, culture theory, and ethnology.

Sapir's scholarly development in linguistic anthropology began in graduate school at Columbia University under the tutelage of Franz Boas, a leader in the development of American anthropology. Boas was interested in the study of the anthropological

approach to linguistics because his own research on Native American languages led him to posit the idea that the culture of a given people reflected the language they spoke. While Sapir's first graduate work was in Germanics, Boas gave Sapir the additional opportunity to study American Indian languages. Sapir continued the technical study of languages throughout his career. Although Sapir's were the Athabaskan languages, he also studied Indo-European, Semitic, and African languages.

Sapir's study of languages led him to conclude that the study of linguistics was a social science rather than a natural science because language was primarily a cultural and social product. Sapir asserted that language serves as the index of the network of cultural patterns of a civilization. He argued that the real world of human beings, to a significant extent, consists of the language habits of a group. Language is therefore a guide to social reality, and only the social sciences could provide a scientific understanding of the relationship between language and cultural phenomena.

Sapir's scholarly contributions to the area of linguistic anthropology emphasized that languages are systematic, complete systems. Sapir conceptualized language as a purely human and non-instinctive method of communicating ideas, emotions, and desires by means of a system of voluntarily produced symbols. In his book *Language: An Introduction to Speech*, Sapir analyzed the elements of speech, the sounds of language, grammatical processes and concepts, and types of linguistic structure. Through such analyses, Sapir set forth his perspective that language was an attribute of humankind, that it is variable in place and time, and that it influences the ways in which people think and behave. One of Sapir's students, Benjamin Whorf, further developed the proposition that there is a systematic relationship between categories of language and thinking. Eventually this idea was termed the Sapir-Whorf Hypothesis.

Sapir was also a cultural theorist who was keenly interested in the relationship of personality to culture. Indeed, scholars consider Sapir as one of the first theorists to examine the interplay of culture and personality. While linguistics influenced his thinking as a cultural anthropologist, Sapir's work in this area significantly considered the importance of psychology and psychiatry. He wrote several essays in which he examined such topics as cultural anthropology and psychiatry, the concept of personality, and the

relationship between culture and personality. In these essays, Sapir clearly distinguished the apparent differences in the subject matter and purposes between cultural anthropology and psychiatry. However, he saw the service that anthropology could provide to psychiatry because the variability of cultural patterns demonstrated the elasticity of human behavior and the problematic nature of the concept of “normal behavior.”

SAPIR-WHORF HYPOTHESIS

Edward Sapir (1884–1939) and Benjamin Lee Whorf (1897–1941) developed the idea known as the Sapir-Whorf Hypothesis. Sapir and Whorf posited that the particular language we speak influences the way we see reality because categories and distinctions encoded in one language are not always available in another language (linguistic relativity). Scholars also interpret the hypothesis as standing for the proposition that differences in the structure of languages produce differences in how people think (linguistic determinism). However, neither theorist specified exactly the relationship between language and thought; that is, whether he believed that language determines thinking or just influences it. Consequently, because of its lack of specificity, the Sapir-Whorf Hypothesis has been a controversial idea since its inception in the 1920s and 1930s. Scholars in a variety of disciplines, including anthropology, education, linguistics, philosophy, and psychology, have disagreed about the role of language in thinking and how Sapir and Whorf intended to conceptualize that

relationship. They have conducted research based on their conceptualization of the Sapir-Whorf Hypothesis in the hopes of finding empirical evidence to support it. However, research findings remain inconclusive, and the Sapir-Whorf Hypothesis is a subject that scholars continue to investigate.

From his studies of the research of Wilhelm von Humboldt and his own research on languages, Sapir concluded that there is clearly a connection between language and thought; however, he did not clearly state whether he believed that language determined thought. Rather, he argued that no two languages are ever sufficiently similar such that they could represent the same reality. Instead, he posited that the worlds in which different societies live are distinct worlds, not merely the same world with different labels attached to them. Furthermore, Sapir believed that we see and hear and otherwise experience the world very largely as we do because the language habits of our community predispose certain choices of interpretation.

One of Sapir's students, Benjamin Lee Whorf, further developed the proposition that there is a systematic relationship between categories of language and thinking. Many scholars attribute the development of the Sapir-Whorf Hypothesis to Benjamin Lee Whorf. Whorf was not an academic linguist but a fire insurance inspector; the study of linguistics was his avocation. Whorf studied the Hopi language under the supervision of Sapir. He developed a theory in collaboration with Sapir that many scholars identify as extreme Whorfianism. Extreme Whorfianism states that the structure of a human being's language determines the manner in which a person understands reality and behaves with respect to it. Whorf argued that we categorize nature along lines laid down by our native languages. Thus, for example, Whorf believed that speakers of Chinese dissect nature and the universe differently from Western speakers. In sum, Whorf believed that the culture of a people determines their language and their language determines the way that they categorize their thoughts and their experiences in the world.

Although Sapir and Whorf described a relationship between language and thought and culture, neither of them formally wrote a hypothesis that specified a relationship that scholars could subject to rigorous empirical testing. Instead, they proposed broad definitions and gave examples from their research to illustrate their arguments. Indeed, scholars formally named the ideas the Sapir-Whorf Hypothesis

only after the deaths of Sapir and Whorf. Yet the hypothesis remains an authoritative but controversial statement primarily because of its two central principles: linguistic relativity and linguistic determinism.

The principle of linguistic determinism is troublesome to many scholars and a source of criticism. This principle posits that we construct our thoughts based upon the language that we speak and the words that we use. In its strongest sense, linguistic determinism means that language determines thought; that is, humans may be able to think only about objects, events, processes, and conditions that have language associated with them. In this view, language and thought are identical. In its more moderate sense, language partially influences thought because the culture of a society influences its language. The writings of both Sapir and Whorf do not specifically commit them to a particular position on this issue.

Many scholars believe, based on their interpretations of his writings, that Whorf committed to a strong version of linguistic determinism; that is, that language determines thought and, consequently, thought is not possible without language. Scholars have challenged this strong determinism view on both theoretical and empirical grounds. Some scholars criticize the strong version of linguistic determinism from the perspective of causality; that is, how does one determine whether language has affected thought or thought has affected language? In order to make such a determination, one must separately observe thought and language, an observation that is virtually not possible. Additionally, they argue, if there is no thought without language, then how did language develop initially? A third criticism concerns translatability; that is, scholars argue that although languages may differ in the way they express certain details, a concept can always be passed on between languages, contrary to what a strong version of linguistic determinism would hold. While it may be true that the sense or connotation contained in a word may be lost in translation, the fact that the concept can be translated supports a more moderate view of the relationship between language and thought. Fourth, there is the issue of codability, or how many words it takes to express a concept or term in one language. Those who support the strong version of linguistic determinism argue that the fact that a culture has only one word for something that would take others ten words to express must mean that different thinking occurs. However, other scholars indicate that

this does not mean that two people see the world differently; rather again, codability illustrates the idea of language partially influencing thought. Finally, there is the theory of universals, attributed to Noam Chomsky, that argues that there are deep structures common to all languages. In this view, all cultures are related and have similar realities.

Given the above criticisms, few scholars today would accept the strong formulation of the Sapir-Whorf Hypothesis. Most scholars subscribe to a moderate or weak form of linguistic determinism, one that posits that language influences thought but does not determine it. This view accepts the principle of linguistic relativity; that is, that there is a close relationship between the structure of a language and the culture that uses that language. In this view, language influences the way we think and it influences us to look at the world in a certain way.

Linguists and anthropologists have long recognized the importance of language to culture. The Sapir-Whorf Hypothesis explains that different cultures understand and appreciate the world in different ways and that language is the vehicle to express that difference. Today, while linguists and anthropologists generally agree that language influences thought, they do not believe that it determines thought. However, scholars continue to examine how language influences thought. Therefore, as a theory of linguistic relativity, the Sapir-Whorf Hypothesis remains a significant and substantial contribution to the fields of linguistics and anthropology.

SARDINIA

Sardinia is a large island in the middle of the western Mediterranean Sea. Close by, to the north, is the smaller island of Corsica; to the southeast is Sicily. Sardinia has been a part of Italy for more than a hundred years, but the Italian peninsula is a fair distance across the sea to the east. Before going to Italy, Sardinia was controlled by Spain; before that Byzantium; earlier the Vandals, who came after the Romans. In recent centuries, Sardinia was regularly raided by Saracen Moor pirates; the Sardinian flag, called “quatro mori,” features four captive black Moors with blindfolds.

Sardinia has a Mediterranean climate of wet, mild winters and hot, dry summers and Mediterranean vegetation of oak forests, which have been much cleared by human action to provide open pasture and agricultural land as well as human settlements. Traditionally cultivation has focused on Mediterranean crops: wheat, tomatoes, olives, and grapes; livestock are predominantly sheep, and also goats and pigs, with some cattle and horses. The corresponding Mediterranean diet common to Sardinia is bread and pasta, olive oil, tomato sauce, wine, sheep’s and goat’s milk cheese, prosciutto, lamb, mutton, and pork, supplemented by vegetables and fruits.

Today, a million and a half Sardinians (*sardi*) are spread across the island in many agropastoral towns, some exceeding ten thousand inhabitants. The two main cities are Cagliari, the capital, on the south coast, and Sassari in the north. The two main geographical features are the great Campidano valley running up the west of the island and the massive Gennargentu mountain range and plateau filling most of the eastern half of the island. Between valley and mountain, history and culture divides. The rich agricultural Campidano valley, bread basket of the Romans, was always the great target and prize of foreign invaders and imperial conquerors, and

the culture was one of a beleaguered peasantry. The rugged mountains, home of escapees from the plains, resisters, rebels, and *banditi*, was friendlier to the *pastore* (shepherd) with his flock, than to large-scale agricultural production.

Sardinians have always identified strongly with their local community (*il comune*), which commonly includes a main settlement, water sources, pasture, forest, agricultural land, gardens, and orchards, and may include offshoot settlements and, today, light industries. Intended by design to be self-sufficient—a common ambition in the traditional Mediterranean Europe—these communities tended to be closed and

Source: © iStockphoto/Janine Bolliger.

inward looking: endogamous in marriage, agonistic with other communities, chauvinistic about the special virtues of each. All Roman Catholic, all speaking *Sardu*, a language derived from Latin (with the exception of a few small pockets of Spanish and Greek speakers), all depending on agropastoral production, all with similar customs, dress, and norms, the *comuni* differentiated themselves from each other by minor differences in dialect, cuisine, and politics. But they shared, especially in the mountain *comuni*, a fierce independence at the community and family levels. In the mountains, they followed a strict code, called the *codice barbaracino*, named for the highland region of Barbagia, which dictates individual “self-help,” *vendetta*, in response to insult or attack, vengeance in relation to injury to honor, property, or person, and neutrality and silence by anyone not directly involved.

Since WWII, mass media and education, as well as labor migration, have substantially Italianized Sardinia. Standard Italian is taking the place of Sardinian, and traditional agropastoral work has declined in prestige in favor of modern, salaried, “clean” office work. Young Sardinians complain that they “don’t want to be *contadini* (peasants).” And yet, great value is still put on *genuino* (pure) water, food, and relationships. Sardinians today are torn between the modern and the *genuino*.

SARTONO (1928–1995)

Sastrohamidjojo Sartono was one of the founders of modern geology and paleoanthropology in Indonesia. He was born in Madiun (East Java) on June 30, 1928, and died suddenly during a research visit to the Netherlands on October 25, 1995.

In the fall of 1956, Sartono received his BSc in mathematics and natural science from the University

of Indonesia, and in the fall of 1958 he received his doctorate in science and geology from the Natural Science University in Bandung, Java. His dissertation was titled “The Stratigraphy and Sedimentation of the Most Eastern Part of Gunung Sewu (East Java).”

Sartono accepted the position of lecturer with the Department of Geology at the University of Indonesia at Bandung in the fall of 1956. Then, in the fall of 1959, he became professor of geology when the University of Indonesia at Bandung became the newly formed Institute of Technology Bandung (ITB). He remained professor of geology and paleoanthropology at ITB until his death.

Sartono devoted his life to the study of the Sangiran site, as well as other sites in Java and other Indonesian islands. He had received training in paleoanthropology from G. H. R. von Koenigswald and many other scientists from Europe and Japan, and he continued the practice, begun by von Koenigswald, of training local farmers to identify faunal remains. Nearly all of the hominid remains found in Indonesia were discovered by local farmers working the fields, and by working with them, Sartono recovered nearly all of the fossil hominids known in Java. Without his work, the fossil record from Indonesia would be very small. Sartono received numerous awards and recognitions for his research and published numerous articles in scientific journals.

SASQUATCH

Sasquatch, Bigfoot, and the Yeti are all varieties of bipedal human-like primates whose existence has yet to be proven. Reports of the creature known as Sasquatch date back to the ancient legends of Native Americans living on the west coast of the Americas,

from northern California to British Columbia. Photographs, eyewitness accounts, film, footprints, and audio recordings have been collected sporadically over the past two centuries. Yeti sightings in the Himalayas date back to 1887, and Bigfoot sightings on the west coast of the Americas have been reported since the early 1800s. None of this evidence, however, has ever conclusively proven the existence of this creature, and in many cases, especially in the latter half of the 20th century, the evidence was proven to be a hoax.

It is possible that such creatures exist, but major doubts have been raised. The biggest obstacle is the lack of a body; no Sasquatch capture (dead or alive) has ever been thoroughly documented and scientifically analyzed. At one point in our history, primates did live in North America, but not during our recent history. No fossil evidence shows the existence of primates in North America later than 22 million years ago. Furthermore, of the primate fossils that were created over 22 million years ago, none of them were ape sized. Also, there exists no fossil evidence of a non-human hominoid in the western hemisphere. The Sasquatch phenomena has become wildly popular for a number of reasons; perhaps the biggest is the possibility that this creature represents the missing link in the chain of evolution that Darwin predicted. The problem is that this hypothesis requires a gradual development over time from either a gorilla or another large ape that walks on all fours to a bipedal Sasquatch. There would have to be a series of inter-connecting species, for which no fossils have been found. Also, in order to maintain its species, the Sasquatch would have to reproduce, and without a sufficiently large population, there wouldn't be enough genetic variation to sustain the species. Without sufficient genetic variation, any species becomes more likely to succumb to recessive genetic disorders. As long as the aura of public interest continues to surround the subject, and as long as startling yet unreliable eyewitness accounts and other such evidence appear, it will be impossible to disprove the existence of such a creature. Since disproof is highly improbable, the question of this creature's existence puts the burden of proof on the advocates of a Sasquatch theory; however, to date no incontrovertible empirical evidence has been found. Such evidence as blood, hair, skin, or droppings would be far more suited to proving the existence of this beast, for such evidence would provide a DNA sample for study

and interpretation. Until such evidence is found, the existence of the Sasquatch remains a hypothesis for anthropologists.

DE SAUSSURE, FERDINAND (1857–1913)

Swiss linguist Ferdinand de Saussure was the founder of structural linguistics, which broke with philological and historical approaches to language to establish a new approach to language based on the understanding that “language is a form, not an essence.” In defining language as a system of signs, he also became the father of modern semiotics. His notion that the meaning of a sign is to be found in its relation to other signs laid the foundation for the structuralist school in linguistics, semiotics, and social theory.

Born November 26, 1857, in Geneva, Switzerland, Saussure could read and write five languages by the time he was 15 years old. He attended the University of Geneva and the University of Berlin before receiving his PhD at the University of Leipzig in 1880. In 1879, while still a student, he made his reputation with a brilliant contribution to historical linguistics, *Memoir on the Original System of Vowels in the Indo-European Languages*, which theorized about how vowel alternations take place in Indo-European languages.

Saussure proceeded to teach in Paris at the École Pratique des Hautes Etudes. He then returned to Geneva and became a professor of Indo-European linguistics and Sanskrit and general linguistics at the University of Geneva from 1891 to 1912. He wrote no other books but was enormously influential as a teacher. He is best known for the *Course in General Linguistics*, a book constructed from notes of his lectures taken by students.

The *Course* is brimming with ideas. Saussure broke with the dominant comparative-historical school of his day by pointing out that the historical origins of

Source: Courtesy, Library of Congress.

language are irrelevant to the ways people actually use language to communicate. The fact that “beef” is an Anglicization of a Middle French word that entered into English after the Norman conquest is completely unnecessary for understanding its use in contemporary speech. Saussure argued that in addition to *diachronic* studies of language evolution, there was a need for a synchronic linguistics that would describe languages as they work in contemporary life.

Perhaps his most influential contribution to linguistic and social theory was his distinction between language (*langue*) and speech (*parole*). Language, for Saussure, is the signifying system through which we communicate. Speech refers to actual utterances. Because we can communicate an infinite number of utterances, it is the system behind them that is important. Saussure illustrated this with reference to a chess game. The chess game has its rules and its pieces and its board. These define the game. Actual games of chess are only interesting to the participants. Thus while linguists may collect data from actual instances of speech, the goal is to work back to the system of rules and words that organizes speech.

Only slightly less important was his notion of the arbitrary meaning of the sign. Any word, Saussure

said, is a sound that stands for an idea. The word *tree* does not refer to the thing in the world but rather to a concept we have in our heads. The same concept can be represented by many different words in different languages because the relationship between any given sound and the idea it signifies is arbitrary—it is created by society.

Although both Saussure’s *langue/parole* distinction, and his insistence on the arbitrariness of the sign have been criticized, his influence has been remarkable. The structuralist movement in anthropology, cultural studies, linguistics and literary theory, and social theory derive from his work, as do, in a less direct way, the influential deconstructionist and post-structuralist work of Roland Barthes, Jacques Derrida, Michel Foucault, Julia Kristeva, and Jacques Lacan.

SCHALLER, GEORGE B. (1933–)

The next time you have the good fortune to see an endangered species, you might be the beneficiary of George Schaller, a naturalist who has become well-known for his efforts to describe and preserve animals who are in danger of extinction. George Schaller was born in Berlin, Germany, but found himself in Missouri as a teenager. He later received his doctorate from the University of Wisconsin. His interest in non-human species began during his childhood and has continued through his interesting adult life. He has traveled extensively throughout the world and studied various types of animals. These travels and studies provided him with the material needed to write numerous books and articles. One of his publications, *The Mountain Gorilla: Ecology and Behavior* (1963), provided valuable information about the

activities of gorillas in the wild that had previously not been available. His successful professional activities have also resulted in numerous awards including the National Book Award in 1973 and the World Wildlife Fund Gold Medal.

George Schaller is also important for his attempt to protect animals from possible extinction. Those of us who are concerned about improving our environment and protecting the many species of animals whose presence is endangered will find George Schaller to be someone well-deserving of our praise. His works provide valuable information for future generations of individuals who have an interest in animal conservation, and serve as an inspiration to many of us to work for the improvement of our natural wildlife environment.

SCHLIEMANN, HEINRICH (1822–1890)

Heinrich Schliemann was born January 6, 1822 in the vicarage of Neubukow, Germany, and died December 26, 1890 in Naples, Italy. Most of his ancestors were vicars, traders, and farmers. His father was a poor and violent vicar, and his mother, who died when he was nine, took care of their nine children. According to Schliemann's autobiography, when he was given a book on world history for Christmas, he promised his father he would excavate Troy.

Schliemann left school after graduating from junior high school. For several years he worked in a grocery and then as a bookkeeper in Amsterdam. As he had a great interest in languages, and a great

talent for learning them, he became fluent in reading and writing a great number of them—estimates differ from eight to sixteen languages. In 1846, Schliemann, who spoke Russian, founded an office for an Amsterdam trading firm in St. Petersburg, and the city was his primary residence until 1864. There he also founded his first trading company in 1847, the same year in which he became a Russian citizen. In 1851/52, Schliemann traveled to California to search for his younger brother, Ludwig. After his return to St. Petersburg, he married Jekaterina Petrowna Lyschina (1826–1896), with whom he had three children. During the Crimean War (1853–1856) his business flourished, and he made an enormous profit; however, during the first worldwide economic crisis, in 1857/58, he suffered heavy losses.

In the following years, he traveled through many countries in Europe, North Africa, and the Near East, and considered giving up business to dedicate himself to other goals—he received great satisfaction from reading Sophocles, Homer, Horace, and Virgil. In 1864, Schliemann and his wife were made hereditary freemen of St. Petersburg, and he also closed down his trading firm—by that time, he was extremely rich. Between 1864 and 1866, he undertook further extensive journeys through Asia and North and Central America, after which he decided to become a resident of Paris. There he stayed until 1870, and studied philology, philosophy, archaeology, and literature. His first book, *La Chine et la Japon au Temps Present*, was published in 1867. In 1867/68, he visited North America, Italy, Greece, and Turkey. In the meantime, his wife and children remained in St. Petersburg. In 1869, he published his second book, *Ithaka*, in which he compared various contemporary locations to those mentioned in Homer. The same year, he received his doctorate from the University of Rostock (in absentia), became a citizen of the U.S., divorced, and married a young Greek schoolgirl named Sophia Engastromenos (1852–1932), with whom he had two children.

Schliemann's history of excavations started in 1870. Without permission, he led an excavation in Hisarlik (Troy) but was driven away after ten days. From 1871 until his death in 1890, his primary residence was Athens. In 1871, his groundbreaking excavations in Troy began. Seventy to eighty Greeks were employed to actually do the digging. In his diary, Schliemann noted that he was the first to ask the question whether there had ever been a Troy, not only

Source: Courtesy, Library of Congress.

theoretically but also practically. In his first book on Troy (*Ilios*), he refers to his own method as “research by pickaxe and spade” combined with a love for the ancient classics, in particular, Homer. One could also describe his method as the visualization of myths at authentic locations, a method which does have a long history. What dissatisfied him with respect to archaeology was that it was done slowly and carefully so that little progress was made. Instead of removing one layer after another, he wished to simply dig deeper and deeper. Luckily, after being advised in a letter by the French archaeologist Emile Burnouf, he wrote down the location of his findings. And his findings were immense. By 1873, he had dug up two-thirds of the city and found “Priam’s Treasure.” He also claimed that his findings proved that the *Iliad* was based on actual events, and his firm belief in the historicity of the Trojan war was the reason behind all his excavations.

He published his findings in 1874 under the title *Trojanische Alterthümer*. The public showed great

interest in his work; however, the reaction of the scientific community was less enthusiastic and rather skeptical. In 1875, he gave presentations in many major European cities, as he was a well-known man by then. As a consequence, he was awarded honorary membership in the Society of Antiquaries of London (1876), the *Deutschen Anthropologischen Gesellschaft* (1877), and the *Berliner Gesellschaft fuer Anthropologie, Ethnologie und Urgeschichte* (1881). He continued to lead excavations. In 1876, he received permission to dig in Tiryns, Mykene, and Orchomenos. A year later, his book, *Mykenae*, was published, and his Troy collection was exhibited in London and then transferred to Berlin in 1881. As a consequence of his enormous success, he received further great honors: in 1881, he was made freeman of Berlin, and he was awarded an honorary doctorate by Oxford in 1883.

In 1876, his method for excavations was still to dig without considering the various layers but with his mind solely focused on setting free the monuments of a particular period—a method of which the Greek archeologist supporting him, Panagiotis Stamatakis, was very critical. In Mykene also, Schliemann managed to dig out many precious treasures and interesting sites, which he always connected to stories passed down from ancient times.

After the archaeologist Frank Calvert and the Oriental scholar Archibald Henry Sayce informed Schliemann of their interpretation of the various layers he had excavated, Schliemann attempted to identify the seven layers he had found himself, and he published his reflections in his book *Ilios*. He concluded that work by stressing that he hoped that his “research by pickaxe and spade” proved that the events described in Homer’s poems actually did take place. There he also stresses that he never doubted the unity of the Homeric poems and that the *Iliad* and the *Odyssey* were composed by one man only.

In the following years, he excavated in Marathon, Tiryns, Orchomenos, Alexandria, and Troy. In 1890 he became deaf and had an ear operation in Halle, after which he left the city, although his physician advised him not to. On December 24, 1890, he visited Pompeii; on the 25th he had a breakdown while on the way to visit a doctor. Ten days before his 69th birthday, on December 26, he died in Naples. After his death, his books *Bericht über die Ausgrabungen in Troja im Jahre 1890* and *Selbstbiographie–Bis zu Seinem Tode Vervollständigt* were published. In the following years, the archaeologist Wilhelm Dörpfeld

continued to excavate in Troy, financed by Schliemann's wife, Sophia.

Irrespective of Schliemann's great findings, many critics doubted that he was a proper archaeologist. However, there were others, like Sayce, who held that Schliemann's research by spade began a new era for the study of classical antiquity.

SCHMIDT, WILHELM (1868–1954)

Although he was born into humble circumstances in Hörde, a small town in Westphalia (western Germany), Father Wilhelm Schmidt became a life-long student of the world as a leading authority in his day on linguistics, ethnology, and comparative religion. At the age of 15, he entered the mission school of the Society of the Divine Word (*Societas Verbi Divini*, SVD), at Steyl, in the Netherlands. This seminary was established in 1875 by Father Arnold Janssen for the training of Roman Catholic missionaries; Schmidt completed his education there and was ordained into the priesthood in 1892. After he studied Semitic languages at the University of Berlin for 2 years, Schmidt began teaching at the new SVD seminary in Mödling (near Vienna), Austria; he held this post from 1895 until 1938, when he left Austria because of the Nazi takeover.

Schmidt developed a special interest in the languages spoken in regions where his SVD colleagues served (i.e., North and South America, Europe, the Far East, and Oceania); he obtained the support of Janssen to publish a journal that would advance this missionary endeavor and promote anthropological studies. In 1906, Father Schmidt launched

Anthropos: International Review of Ethnology and Linguistics; the year 2005 witnessed the publication of *Anthropos*, Volume 100. This journal, which has published thousands of articles and reviews, remains one of Schmidt's greatest contributions to anthropology. From the beginning of his work as professor and editor, Schmidt encouraged missionaries to become better students of the people groups among whom they worked—and to advance the study of *Völkerkunde*, the world's cultures and languages.

In addition to his teaching and editorial work, Father Schmidt helped to start the Vatican's Ethnological Missionary Museum; this collection was established in 1926 and was directed by Schmidt from 1927 until 1939. During this same period, he founded the Anthropos Institute and Library at Mödling/Vienna as another means to advance his religious-apologetic-anthropological agenda; Fathers Wilhelm Koppers, Paul Schebesta, and Martin Gusinde, also SVD clergy, helped establish this research center. When the *Anschluss* occurred, Schmidt transferred the Anthropos Institute and its library to Fribourg, Switzerland, where it remained from 1938 until 1962. By 1962, the Society of the Divine Word moved their Institute to Sankt Augustin, outside Bonn, where it remains today. Wilhelm Schmidt also taught at the University of Vienna (1921–1938) and at the University of Fribourg (1939–1951). Over the course of his professional career, Father Schmidt was in constant contact with coworkers from different parts of the world and applied his comparative perspective and linguistic skills in many research projects. He published over 600 books and articles and received honorary degrees from six universities.

Schmidt's initial scholarly activity focused on linguistics, including the languages of Papua New Guinea—one of the places where SVD missionaries worked. He expanded his study to include Oceania (including Australia) and identified connections between “Austronesian” (formerly Malayo-Polynesian) languages and those spoken in Southeast Asia; Schmidt named this family the “Austro-Asiatic” languages.

Father Schmidt also made significant contributions to the field of cultural anthropology and was a leading figure in the German school of Diffusionism, along with Frobenius, Graebner, and Ratzel. In opposition to theories of cultural evolution, these—and other scholars in Europe and America—proposed a system of “culture circles” (*Kulturkreise*), by which

cultural traits diffused outward from their points of origin. This historical-geographical emphasis, which was worked out in great detail, countered the theory of unilinear evolution but did not hold up under close scrutiny. Nevertheless, the “Vienna Cultural-Historical School” exerted great influence on the development of anthropological theory, including advocates of the “American Historical Tradition” (e.g., Boas and Kroeber), and avoided the excesses of the British diffusionist school (e.g., Rivers and Smith). One of Schmidt’s best known books, available in English translation, delineates his views (*The Culture Historical Method of Ethnology: The Scientific Approach to the Racial Question* [1939]) and partially explains his conflict with the National Socialists.

Though he wrote many books and articles, published in the *Anthropos* journal and elsewhere, there is no doubt that Schmidt’s greatest work is his 12-volume magnum opus, *Der Ursprung der Gottesidee: Eine historisch-kritische und positive Studie*. This study is a compilation of an enormous body of data, and its production occupied much of his career—from the appearance of the 1st volume in 1912 until the 12th volume in 1955. In this collection and analysis of a vast array of religious traditions (reminiscent of the range of illustrations treated by Frazer or Eliade), Schmidt attempted to prove (à la Andrew Lang) that the religions of the technologically primitive (or “ethnologically oldest”) peoples include a “monotheistic” trend. In short, he was attempting to demonstrate that the widespread recognition of a “High God” reflected the original monotheism of the Bible. This view has not been widely accepted by specialists in the anthropological and historical study of religion, and many scholars have given up their attempt to discover the religious *primordium*. In the end, Schmidt, who rejected an evolutionary explanation of culture and religion, fell back on a similar method—that is, assigning cultural and religious levels to a theoretical historical sequence. The monumental *Ursprung der Gottesidee* is available only in German, but two English titles that reflect Schmidt’s work in this area are *The Origin and Growth of Religion* (1931) and *High Gods in North America* (1933). These and his other works reflect important stages in the history of anthropological theory—and in the rise and development of “missionary anthropology.”

SCHNEIDER, DAVID M. (1918–)

David Murray Schneider was among the leading contributors to symbolic anthropology and the study of kinship. He defined culture as a system of meanings and symbols and emphatically distinguished culture from the social system. Schneider also made important contributions to Micronesian ethnography. From the 1960s through the mid-seventies, he was a powerful force in the University of Chicago’s anthropology department. He was instrumental in founding the Association for Social Anthropology in Oceania. And, through his analysis of kinship as a cultural system, he became arguably the most important precursor of postmodernist deconstruction in anthropology.

Schneider was born in Brooklyn, New York, in 1918. His parents were Eastern European immigrants and political radicals. He attended Cornell University intending to major in agricultural bacteriology, but, largely under the influence of R. Lauriston Sharp, he switched to anthropology.

Following a brief stint of graduate work at Yale, Schneider was drafted into the army. Upon his discharge, at Margaret Mead’s urging, he was admitted to Harvard’s new doctoral program in social relations. There he studied under anthropologist Clyde Kluckhohn as well as sociologists George Homans and Talcott Parsons. A period of fieldwork on the Micronesian island of Yap in 1947–48 led Schneider

to conclude that his predecessors' work on kinship was "absolutely all wrong," and he devoted his career to developing an alternative approach.

In 1955, Schneider coauthored with Homans *Marriage, Authority, and Final Causes*, a book that criticized Claude Lévi-Strauss's structural analysis of the prevalence of matrilineal over patrilineal cross-cousin marriage. That led to a vituperative debate with British anthropologist Rodney Needham.

Schneider's most widely cited book is *American Kinship: A Cultural Account*, in which he employed kinship to illustrate his approach to studying culture. He attempted to eliminate prior assumptions, identify the meanings and symbols through which community members define their own cultural units, and use his interpretive insight to elucidate the order underlying his informants' cultural system. The result was a view of kinship that differs from the commonsense perspective held by most American natives but was intended to make that commonsense perspective intelligible to the critical observer. He argued that kinship is a cultural system, not a set of biological facts. Americans use biological relatedness as a symbol in terms of which kinship is defined and differentiated from other cultural domains, but the application of that symbol is not dictated by objective biogenetic reality. Later, he argued that at the cultural level it is impossible to distinguish kinship from such other domains as religion and nationality. Ultimately, he claimed that kinship is merely an anthropological construct that does not exist in any known culture. His last major work, *A Critique of the Study of Kinship*, explored the implications of kinship's (alleged) nonexistence and how the illusion of its existence had distorted cultural analysis throughout the history of anthropology.

SCHWARTZ, JEFFREY H. (1948–)

As an iconoclast and innovative thinker, Jeffrey Schwartz has broad interests in archaeology, anthropology, evolutionary theory, systematics, and philosophy. His undergraduate work involved anthropology and premedical biology, and this was followed by a graduate program in archaeology at Columbia University, where he studied human and animal osteology at archaeological sites in the circum-Mediterranean region. While an external student at the University of London, Schwartz became interested in issues of development and homology, systematics, and fossil primates, focusing on the evolution of vertebrate dentition then under investigation by Jeffrey Osborne. At the British Museum of Natural History, Schwartz worked on Eocene fossil primates, including lemurs, and began to apply information on dental development to lemur phylogeny.

Upon returning to the United States, Schwartz completed his PhD dissertation on "Dental Development and Eruption in the Prosimians and its Bearing on Their Evolution." He then started a collaborative research program with Ian Tattersall at the American Museum of Natural History. At the museum, Schwartz participated in the numerous discussions and talks taking place on systematic theory and evolution. His interest in punctuated models of evolution and cladistic systematics led to an exploration of developmental processes and their phylogenetic implications in a cladistic context. His research on theoretical dental homology led to new approaches to tooth identification and early Eocene primate work. Schwartz also continued to write on general developmental issues such as the role of different cell types in stimulating the growth of structure. By the 1990s, these interests naturally came together in the field of developmental genetics and his proposal for a non-Darwinian model of evolution under the label of "sudden origins." These investigations emphasized the role of developmental genetics in making rapid evolutionary changes and establishing genetic novelty in a species without requiring the external force of natural selection.

In the late 1980s and early 1990s, Schwartz also began to focus attention on hominid evolution. This interest resulted in his well-known and controversial *Red Ape* book, in which he expands on his theory of a common ancestry between orangutans and humans. This theory is also notable for its extremely rare

(among the anthropological and archaeological community) independence from the tyranny of DNA sequence similarity as the last word on phylogenetic relationship. Schwartz's work in hominid evolution has emphasized the relatively superficial level of systematic detail and documentation prevalent in the field of primate paleontology and the practice of some paleontologists of preventing access to fossils by independent researchers.

Schwartz has published about 125 journal articles, chapters, and abstracts and 11 books and monographs. The three-volume series *The Human Fossil Record* provides the first comprehensive and detailed review of the craniodental morphology of Homo and the early fossil hominids. His *Sudden Origins* book integrates population and developmental genetics to show how evolutionary novelty may result in new patterns of biology, behavior, and ecology of organisms while avoiding the teleological mysticism that haunts most evolutionary perspectives in anthropology and paleontology.

Schwartz recently completed the second and revised edition of his *Red Ape* book, in which he provides new critiques of the morphological and genetic issues surrounding the evolutionary reconstruction of human origins. His current research projects include continued work on the systematics and phylogeny of modern and Pleistocene humans, the origins of modern human population diversity, the osteology of ancient Carthage, the craniodental morphology of humans and other anthropoids, and the role of regulatory genetics and development in evolution.

SCIENCE, PHILOSOPHY OF

The philosophy of science is a subdiscipline of philosophy that utilizes the fields of epistemology (how we know what we know) and metaphysics (the fundamental nature of reality, often outside human observational experience) to study the principles and methods of science and the natural world. It seeks to understand the meaning, method, logical structure, and reliability of the scientific way of knowing about the world by developing and testing scientific theories. It also studies the relationships between different sciences and explores the issue of reductionism—the idea that theories of one science (such as biology) can be reduced to those of a more fundamental science (such as physics), or even a “Theory of Everything.”

Science uses a particular approach to knowing about the world and how it works by providing natural explanations for natural occurrences. Scientific explanations come from observations that can be repeated and confirmed by other researchers. Science utilizes the process of discovery; it is open to change as new information is discovered. According to scientific realists, all scientific thinking rests on just a few major principles: a real knowable universe exists, independent of human perception; the universe behaves according to certain predictable laws, without any outside influence; and these laws are knowable through observation and testing. This is the essential nature of science.

Or is it? Philosophers of science debate many of these points, and several schools of thought have emerged that represent or challenge the above position. These include logical positivism, the deductive-nomological model, the hypothetico-deductive method, social constructivism, and postmodernism.

Logical Positivism

Logical positivism developed from the ideas of positivism, epistemology, and mathematical logic. Positivism was derived from the work of French philosopher August Comte (1798–1857), who hypothesized that human culture evolved through three stages: theological, metaphysical, and positive. In the theological stage, humans understand nature through religious superstition and magic. During the metaphysical stage, magic and religion are replaced by

impersonal but unobservable forces. The final positivist stage, according to Comte, is where understanding truly lies: humans rely on observation and experiment to understand nature. Positivists were skeptical of metaphysics in general and many theories involving phenomena that were not directly observable. Logical positivists, however, through the work of Gottlob Frege (1848–1925) and Bertrand Russell (1872–1970), added mathematical logic to the positivist philosophy. Mathematical logic is subject-neutral and, through the use of symbolic rather than linguistic terms, makes it possible to analyze objectively all kinds of concepts.

Logical positivists believe that all the events that take place in the natural world are controlled by the laws of nature. These laws can be determined through the observation of consistencies in the relationships between observable phenomena and make possible the explanation of natural phenomena. They developed the verifiability principle: a statement is meaningful if and only if it can be proven true or false through experience. These statements are proven true or false through mathematical logic, written as material conditionals (mathematical if-then statements). Logical positivists originally required that every element of every scientific theory must be expressed in precise mathematical ways, using definitions called correspondence-rules. These correspondence-rules explain how the nonobservable elements of the theory make a difference to observational experience. If there is no observable difference in result between a theory that includes an unobservable element X and one that doesn't, then, say the logical positivists, there is no evidence that element X is present at all. The correspondence-rule requirement made it necessary to account for every element in the theory in a way that could be verifiable through observation. Therefore, one of the central issues of the positivist approach is the difference between observational terms and theoretical terms.

Logical positivism has developed certain difficulties. For example, the observational/theoretical distinction is often difficult to define. Some observables are too small or large to be observed by humans without instrumentation, which to some make them theoretical. Also, difficulties in writing the correspondence-rules to allow dispositional properties stimulated Carl Hempel (1905–1997) to argue against such a rule in favor of the idea that all the terms in a theory should be understood as an interconnected whole,

rather than individually developed. Additionally, the act of observation or the presence of instrumentation can, in some cases, alter what is being observed, changing its behavior, its fundamental nature, or both. Finally, philosophers such as Thomas Kuhn (1922–1996) have argued that scientists do not, in fact, choose between competing theories in a rational manner using objective facts; rather, their observations are influenced by the theories they are testing.

The Deductive-Nomological Model

The deductive-nomological model of scientific explanation was developed by Hempel and Paul Oppenheim (1885–1977). In this model, the description of the phenomenon is deducible from a set of premises and the laws of nature. The deductive-nomological model sets out four main conditions that must be met for a scientific explanation: the explanation for the phenomenon must be deducible from the set of premises, using mathematical logic; the set of premises must contain at least one natural law necessary for the explanation; the statements composing the set of premises must be empirically testable; and all the laws of nature used must be independently confirmed. This model creates criteria for determining the explanatory power of the theory separate from any subjectivity of the practitioner. However, many philosophers of science argue that there is no true explanation without determination; mathematical logic alone is inadequate to represent the connections between the events in question. The model might allow the scientist to get the pieces of the theory right, but she will not be able to determine which piece is the determining one that explains the phenomenon.

The Hypothetico-Deductive Method

The hypothetico-deductive method, also known as falsificationism, was developed by Karl Popper (1902–1994). It is the model most commonly associated with science today. The method begins with the scientist developing a hypothesis that may explain some phenomenon. The scientist then develops a list of observable predictions that, if true, would support the hypothesis. The hypothesis is then assumed to be true, and a series of experiments are undertaken in an attempt to disprove, or falsify, it. Observations that are contrary to the hypothesis are considered

evidence against it; observations in agreement with the hypothesis are considered evidence in support. It is possible to test competing hypotheses in this manner; a comparison of how well each is sustained by its predictions can lead to acceptance of one over another. Failure to falsify the hypothesis does not prove it, but rather gives it confidence. Repeated failed attempts to falsify a hypothesis lead it to become a more established theory.

However, critics point out that it is unrealistic to imagine that scientific experiments really operate this way. The complexity of the experiment and the world, they say, often make it impossible to isolate one variable to test. Willard Van Orman Quine (1908–2000) raised important concerns about this method. He argued that scientific terms and evidence have to be understood holistically, in that the meanings of scientific terms are introduced in interdependent networks, and only networks of hypotheses can be tested, not individual ones. Since observations, hypotheses, and theories are embedded in our overall understanding, it is not possible to make truly independent observations. Quine and Pierre Duhem (1861–1916) believed that it was often impossible to create experiments that would definitively support one hypothesis over another. The ideas of these two men were combined to form the Quine-Duhem thesis, which states that any observations seemingly contradicting one's hypothesis can always be accommodated to any theory because humans adjust their interpretations of results by altering other, connected beliefs. In other words, it is possible to save the hypothesis by revising the assumptions to accommodate the observation. While this criticism sounds fatal to the method, Quine was pragmatic in his proposed solution: he contended that scientists adjust their hypothesis to maximize its productiveness in generating new predictions, consistency with former beliefs, overall simplicity, and the modesty of the claims. Adjusting the hypothesis in this way maximizes its likelihood of being “true.”

Despite these issues, the hypothetico-deductive method is the most popular scientific approach in use today. However, the controversial Quine-Duhem thesis persuaded some to reject the hypothetico-deductive method in favor of more relativistic approaches. Social movements such as environmentalism and postmodernism, as well as concerns for the social effects of technology, have heightened the interest in the social aspects of scientific inquiry. This has led

many philosophers of science away from the realist view of how science is performed and toward relativist models such as social constructivism and postmodernism.

Social Constructivism

Social constructivists believe that reality and knowledge are not empirically discovered but rather constructed through organized human behavior. Most agree that the world is real and knowable, but they argue that scientific knowledge is socially constructed and people vary in how they understand that world. An extreme version of social constructivism is the idea that humans themselves, through scientific (or other) knowledge, invent the physical universe.

David Bloor, studying what he termed the sociology of knowledge, developed the “Strong Programme” to describe the development, distribution, and maintenance of knowledge. Bloor defined something as “knowledge” if it was taken for granted, institutionalized, or invested with authority by a group of people. The four tenets of the Strong Programme are (a) causality, or what causes knowledge or beliefs to become more or less widely held; (b) impartiality, concerned with all beliefs, true or false; (c) symmetry, in that the same kinds of concepts can explain true or false beliefs; and (d) reflexivity, in that the patterns of explanation can be applied to sociology of science. Bloor argued that truth alone is insufficient to explain why a true belief comes to be held by scientists, but rather social factors play a role. Critics argue that there must be some objective ways to compare true and false beliefs that, while filtered through a social lens, nonetheless reflect an independent material world.

Postmodernism

Postmodernists reject the modernist positivist idea that there is an objective reality about which science holds the monopoly of truth. Instead, they posit that all humans subjectively interpret reality through their experiences. In this view, all science takes place through these filters, and both observations and theories are influenced by them. There is no one true way of understanding the universe, no universal narrative that would justify privileging the scientific explanation for a phenomenon over other explanations. Critics of this model argue that while it is useful

to open science to pluralistic views, it is still critical to maintain an ability to discern legitimate truth from shared belief in untruth, and scientific explanation is not a democratic process.

Postmodernism is heavily influenced by the idea that language and narrative shapes human thought and experiences. David Orr, a postmodernist philosopher of science and proponent of ecological literacy, argues that scientific knowledge alone is insufficient to understand the universe; rather, social issues such as ethics and equity must be included.

While there are some scientists who believe that scientific explanations can be used to explain everything, most believe that science is useful for answering certain types of questions, leaving others to the realms of theology and moral philosophy. Scientific thinking, in whatever form, remains a powerful tool for humans to use to understand the world we live in.

— Cathy Willermet

SCIENTIFIC METHOD

The expression “scientific method” is problematic for several reasons. First, it suggests that there is a single and uniform method employed in all scientific disciplines. However, even a cursory examination of various scientific fields reveals that this is not the case. Secondly, it ignores the historical fact that the general conception of science, including its purported methodology, has undergone changes since ancient times. Finally, it seems to encompass everything that is included in the cognitive processes of science, while in fact there are radical differences between two aspects of scientific cognition: the varied ways in which hypotheses are formed versus the more structured ways in which hypotheses are evaluated.

During the early modern stages of the scientific revolution, three major theories of scientific method

were proposed: the first was the experimental approach advocated and practiced by Galileo and Toricelli, the second was a kind of empirical induction advocated by Francis Bacon, the third was the radical skepticism together with theological assumptions employed by the French mathematician and philosopher René Descartes. In the actual history of science, the evolution of the experimental trend proved fruitful, while the trends initiated by Bacon and Descartes turned out to be largely fruitless in modern science (even though they led to interesting developments in philosophy).

It is generally agreed that there is no recipe for scientific discovery, even though there is some agreement about the requirements for evaluating investigations and explanations. To understand what kinds of requirements are ideally regnant, it is useful to note the contexts in which scientific explanations occur.

To begin with, in any scientific inquiry there is the investigator, or much more commonly a team of investigators, conducting the research. Second, there are facts or problems, which the researcher(s) seek to discover, identify, explain, predict, or control. This factual component may be generated by the researchers, from other sources (such as others in the scientific community), or induced by phenomena occurring in the natural or human world. Third, there are the symbols used to represent the facts together with the symbols (which logicians call “syncategorematic terms”) used to organize and manipulate the factual concepts of interest. Fourth, at any given time there is a system of generally accepted, seemingly well-supported, conceptual schemes (theories, laws, concepts, etc.) that serves as a framework within which the results of the research are expected to fit. Fifth, there are varied sources of information, such as journal articles, conferences, and personal communications. Sixth, there are various rules and procedures, which ideally indicate the necessary logical requirements for making transitions from the factual component to the theoretical component. Following the proposal of F. S. C. Northrup in *The Logic of the Sciences and the Humanities*, one may call these the epistemic correlations. Seventh, there are various evaluative criteria and related procedures that serve to distinguish between scientific and unscientific accounts, or to try to choose the best among competing scientific explanations. This component of the context of scientific investigations includes, but is not limited to, criteria intended to eliminate or minimize

bias. All these criteria may be referred to as the cognitive criteria. Eighth, there is the scientific community, composed primarily of investigators engaged in related fields of exploration. It is this community that should ultimately determine whether an individual scientist, or team of scientists, has obeyed the scientific and logical requirements that they all ideally accept. Of course, there are other things that initiate, guide, encourage, hinder, or prevent scientific exploration, such as funding and moral, social, political, and religious influences. These, however, are not integral components of science itself; they are external impositions. Whether such external impositions are needed, or desirable, is another matter.

Because of their importance in guiding scientific enterprises, the cognitive criteria will now be considered in some detail. The first criteria to be noted are those we may call objectivity criteria, since they are intended to distinguish between idiosyncratic (subjective) and objective features of experience. What is ideally required, although not always possible in practice, is repeatability of observations, experiments, logical and mathematical operations, publicly accessible measurable data, and where possible, double-blind experimental conditions and other safeguards against bias and deceit. Such cognitive restrictions ideally lead to intersubjective agreement among competent colleagues.

Another group of criteria, partially overlapping the objectivity criteria, are those criteria that ideally lead to the identification and rejection of scientifically unacceptable accounts. One group is those accounts for which nothing could possibly count as evidence for or against them. Typical of such pseudoexplanations are fatalistic doctrines. A second group of scientifically unacceptable accounts are those based solely upon gratuitous assumptions or intuitions. A third group of pseudoexplanations, which may seem superficially to be genuine scientific explanations, are those explanations which employ essentially mysterious obscurantist language. A fourth group of defective explanations is those which, other things being considered equal, assume more than needs to be assumed and thus violate the principle of parsimony. Fifth, some putative explanations should be rejected because they are discovered to be internally inconsistent. These five criteria, which serve to identify and discard such scientifically unacceptable accounts, as well as some additional considerations, one may refer to as the eliminative criteria.

Finally, there are criteria that guide scientists in evaluating and choosing among rival scientifically respectable explanatory accounts. These criteria may be referred to as the scientific hypotheses criteria. The logician Irving M. Copi in his *Introduction to Logic* gives one of the best expositions of such criteria. The first criterion is relevance, which insists that minimally from a logically adequate account it must be possible to deduce the fact(s) to be explained. This minimal requirement is, of course, met even by many unscientific explanations. A second criterion is what Copi calls testability. Testability requires that in addition to relevance, a plausible scientific hypothesis must make it possible to predict some other fact. Confirmations of such predicted facts cannot *prove* an account to be correct, although they can increase the likelihood of the account being correct. However, if predicted facts are disconfirmed, then either the account must be rejected or *ad hoc* assumptions must be introduced. The third criterion is compatibility with previously well-established hypotheses, which insists that ideally a scientific account should fit into the framework of accepted science. Fourth, there is the criterion which Copi calls predictive or explanatory power, by which he means the range of observable facts that can be inferred from the rival alternative scientific explanations. If other requirements are equally satisfied by rival hypotheses, but more facts can be deduced from one of them, then this one is preferable. The fifth is logical simplicity, sometimes also referred to as Occam's Razor or the principle of parsimony, which recommends that if rival accounts satisfy the other requirements equally well, then the one making the fewest assumptions is to be preferred.

There are basic presuppositions that form the current dominant scientific worldview, that is, the beliefs about nature and human experience that scientists usually take for granted and which make much of both pure and applied science possible. One of the interesting things about modern science is that most of its predominant presuppositions are really only refined commonsense conceptions:

1. In general, scientists take for granted the reality of space and time, even though in relativity theory they are treated as coordinates in space-time.
2. Scientists also share with common sense a belief in the reality of the material world.

3. Scientists also share with common sense the presupposition that matter (or matter-energy) is quantitative, that is, that matter exists in precise quantities specifiable in terms of conveniently selected units.

4. Another basic presupposition of modern science is the belief that natural objects, including human phenomena, are interdependent, either causally or otherwise.

5. Logically associated in seeking to understand things causally is the presupposition that, on the macroscopic level at least, nearby entities obey uniform, consistent laws.

6. Modern science also presupposes that much of nature can be understood non-teleologically, that is, that much of the natural order, as well as kinds of natural disorder, can be understood and explained without introducing notions of conscious goal-seeking purposes.

7. A similar basic presupposition of modern science is that the universe is intelligible in strictly naturalistic terms. Supernatural beliefs play no role in studying and comprehending nature.

Given the interests of individual researchers or their teams together with their knowledge of problems and contributions of others in relevant fields, and guided by the cognitive criteria and presuppositions, various possible problems and solutions arise. These possibilities are hypotheses—creations of the scientific imagination as to what to expect if certain observations, experiments, calculations, or theoretical elaborations are carried out. Once these creative imaginings have occurred, two additional essential steps in scientific method ideally must occur.

First, researchers must deduce from a hypothesis what might serve as confirming evidence if the hypothesis is correct, or what might serve to refute it if it is not correct.

Second, when possible (and this is not always possible), researchers try to test the hypothesis by seeking the confirming or refuting evidence under controlled conditions that are open to replication and the possibility of intersubjective agreement in the scientific community.

Although this sounds simple and straightforward, in many cases the processes involved are actually very complicated and variable.

All of the disciplines concerned with understanding aspects of human social phenomena try to rely on

dependable cognitive methods, however it is not feasible to suggest that they all succeed in meeting scientific standards. Therefore, the most one can do here is to present a kind of idealized model representing what is involved in the best of social studies.

First, the researchers try to determine the variables to be studied. Second, the investigators seek a hypothesis (a possible relationship between, or among, these variables). For example, if the variables are drug use, poverty, and crimes of certain kinds, what might be sought are possible connections among these variables, or a relationship between or among them. Third, the researchers try to construct a test by means of which changes in the variables can be measured to discover whether the hypothesized relationship among the variables is confirmed or disconfirmed. Fourth, the test is implemented and the results are measured and recorded. Fifth, frequently but not always, these results may be used to form generalizations and to suggest further research. Sixth, members of the scientific community critically assess the protocol employed and suggest further investigations and possibly other hypotheses to explain the findings.

Although the theoretical framework of science will probably undergo significant changes, the basic method of science involving deductions of testable consequences, which has proven to be superior to all rival alleged cognitive methods, will probably remain the same. With the ongoing pursuits of scientists, guided by the cognitive context of science, hypotheses will arise, testable consequences of these hypotheses will be inferred, evidence for and against will be sought, tentative but plausible conclusions will be reached, and these conclusions will form parts of the evolving and naturalistic scientific worldview.

Concomitant with this evolving worldview, there will be new applications that may radically alter the world of everyday life. What effects scientific developments will have on religion, on morality, on economic arrangements, on politics, or on international relations, remain to be seen.

— Tad A. Clements

SCIENTISM VERSUS FUNDAMENTALISM

Both used as pejorative terms by opposing factions, *scientism* and *fundamentalism* imply a mutually exclusive application of the scientific method or religious dogmas to all spheres of human life. What these two otherwise opposite trends share is an uncritical reliance on science on the one hand and religion on the other, so that both groups finally end up having the same attitude toward their guiding principles, making them fetishes.

As Michael Shermer, the publisher of *Skeptic* magazine, puts it, "Scientism is a scientific worldview that encompasses natural explanations for all phenomena, eschews supernatural and paranormal speculations, and embraces empiricism and reason as the twin pillars of a philosophy of life appropriate for an Age of Science." Scientism has been used in its pejorative sense both from an antiscientific standpoint and by supporters of science who argued for a less reductionist notion of science.

As its name suggests, religious fundamentalism seeks to maintain strict observance to the founding principles of a given religion, thus often taking on an antimodernist attitude. Fundamentalism postulates that the texts and dogmas of one's own religion are infallible and precise, in spite of scientific scepticism. The phenomenon of religious fundamentalism is often fed by a sense of alienation from the surrounding society and by the complexity of modern society. As Richard Antoun has pointed out in his study *Understanding Fundamentalism: Christian, Islamic and Jewish Movements* (2001), Christian, Muslim, and Jewish fundamentalists share the same worldview, which is based on the infallibility of the scriptures and expresses outrage at the pace and extent of modern secularization.

Fundamentalism has especially come to refer to any religious enclave that intentionally refuses to be identified with the larger religious group in which it originally arose. This is because the fundamental principles upon which the larger religious group was founded have been distorted by alternative principles. Fundamentalism is thus on the rise in our contemporary societies, where

traditional religions have lost their influence on the majority of people, but where science is unable to offer all the answers once supplied by religious beliefs. The spreading of religious sects and cults in the most industrially advanced countries is evidence of the strength of the fundamentalist sentiment even where scientism and rationalism seemed to have weakened religion.

— Luca Prono

SCOPES, JOHN (1900–1970)

John Scopes was the defendant in the 1925 case *State of Tennessee v. John Thomas Scopes*, a landmark in the contentious history of evolution education in the United States.

Scopes was born on August 3, 1900, in Paducah, Kentucky. Following a brief stint at the University of Illinois at Urbana, he enrolled at the University of Kentucky at Lexington, where in 1922 he witnessed his professors successfully lobby against a proposed antievolution bill in the Kentucky legislature. After receiving a BA in law in 1924, he accepted a position coaching football and teaching algebra, physics, and chemistry at Central High School in Dayton, Tennessee.

In Tennessee, teaching evolution in public schools and universities was prohibited by the Butler Act, enacted on March 21, 1925. Wishing to challenge the law, the American Civil Liberties Union offered to represent anyone willing to be the defendant in a test case. Sensing the opportunity to publicize their town, a group of Dayton civic leaders approached Scopes. Although he was unsure whether he had actually taught evolution, he disapproved of the Butler Act and consented to be involved. He was arrested on May 5 and indicted on May 25, 1925.

The case became a media circus, with national figures such as William Jennings Bryan and Clarence Darrow commanding the spotlight; during the preparation for the trial, a reporter commented, "Poor little Scopes was almost forgotten." In the trial itself (July 10–21), the defense stipulated that Scopes taught evolution. "So I sat speechless," he later observed, "a ring-side observer at my own trial, until the end of the circus." After he was found guilty and fined \$100, he

spoke for the only time during the trial, calling the statute unjust and pledging to continue to oppose it. On January 14, 1927, his conviction was overturned on appeal on a technicality, and the state's attorney general declined to prosecute him again.

After the trial, Scopes enrolled in the PhD program in geology at the University of Chicago. Owing to his notoriety, he was refused a fellowship in 1927; the fellowship's administrator advised him to take his "atheistic marbles and play elsewhere." Turning to commercial work, he worked for Gulf Oil of South America for three years, mainly in Venezuela, where he married Mildred Walker in 1930. To please his bride, he converted to Roman Catholicism, but remained an agnostic; the couple had two children.

Returning to the University of Chicago in 1930, Scopes began work on his dissertation, but was prevented from completing it by financial woes. He worked as a geologist for the United Production Corporation, later the United Gas Corporation, from 1933 to 1964. In 1960, he was persuaded to help in promoting the film *Inherit the Wind*, a cinematic version of the 1955 play loosely based on the trial, in which Scopes is represented by the character Bertram Cates. His memoirs, published in 1967, aided in the repeal of the Butler Act the same year. He died in Shreveport, Louisiana, on October 21, 1970.

SELECTION, NATURAL

In Charles Darwin's theory of natural history, selection is the principal mechanism that is responsible for the evolution of life on Earth.

Three conditions must be met if natural selection shall occur in an ecological system. First, organisms living in the system must show phenotypic variations that bear upon their survival. Second, those variations must be heritable. Third, the environment must constrain the growth of the populations in the ecosystem by placing only limited feed resources at their disposal.

Whenever all three conditions are fulfilled, natural selection will occur among the organisms. They must then compete against each other for the scarce resources. The better an organism is adapted to its environment, the higher its chances are to get more resources and, finally, to have more offspring than its rivals. The number of adult offspring of an organism is called its "fitness." The fitter an organism is, the higher the relative frequency of its genes in the genetic pool of its population is, so that, in the long run, some genes will be present only in a few organisms or will even totally disappear. Natural selection has sorted them out—and not some mysterious drive to perfection inherent in living nature (as supposed, for example, by Jean Baptiste de Lamarck's famous pre-Darwinian evolutionary theory).

The process of natural selection applies also to the biological origin of *Homo sapiens sapiens*. Evolutionary anthropology must therefore recur to natural selection as an explanation for the genetic endowment of the first human beings.

That the history of life on Earth has to be explained by natural selection was claimed simultaneously and independently by papers of Charles Darwin and Alfred Russel Wallace, which were presented at a meeting of the Linnean Society in London on July 1, 1858. Both naturalists were inspired by Thomas R. Malthus's *Essay on the Principle of Population* (1798). They transferred Malthus's crucial idea that population growth is geometrical but food increase only arithmetical, from human to natural history. As a meticulous naturalist, Darwin thought over evolution by natural selection following his return from the voyage on HMS *Beagle*, but only after Wallace had sent Darwin a paper on the same idea, could he be urged by his friends to publish a first systematic account of his thought, *On the Origin of Species by Means of Natural Selection, or the Preservation of Favoured Races in the Struggle for Life* (1859). This work has to be honored as the birth certificate of modern evolutionary theory.

The first five chapters of *The Origin of Species* infer the hypothesis of natural selection. Chapters 6 to 13

document its explanatory power by deducing and checking its consequences for specific biological problems, so that the theory of evolution by natural selection can be affirmed as well grounded in Chapter 14.

Darwin's inference of the hypothesis of natural selection brings together four sets of empirical data. The first set contains the wealth of experience in artificially selecting parents for breeding plants and animals that shall show some desired properties. The second set includes facts about the variability of organisms of the same species. If heritable, such variations constitute the material on which natural selection can act. The third set comprises data on ecological restrictions that force organisms to struggle for survival. The fourth set consists of empirical data about reproduction and heredity, by which variations are transmitted from a generation to the next one in proportion to the fitness of the varying organisms.

Knowing the laws of variation, heredity, and ecological dynamics, and given sufficient data about present-day biodiversity, the Darwinian biologist should be able to deduce that natural selection is the principal mechanism by which life on Earth has evolved. Darwin himself did not know those laws—especially he did not know the laws of genetics. But in principle the hypothesis of natural selection is a deductive conclusion from premises discovered by the analysis of the above-mentioned data sets. It is therefore unnecessary to posit a principle of natural selection as a kind of not provable axiom for biology. It is even false to do so, since such a principle would limit natural selection to a particular class of entities, which are called “organisms.”

Nowadays it is possible to explain the mechanism of natural selection as an effect of general natural laws that act upon systems consisting of self-reproducing varying elements under restrictions on growth (Manfred Eigen). Darwin's natural selection is then just one instance of this more general selective process—with organisms as self-reproducing elements, genetic differences as variations, and the environment as a set of restrictions on the system's growth.

Selection is generated by a natural dynamics that, on the one hand, can be described formally without referring to the history of life on Earth, and that, on the other hand, states what conditions real evolution must meet if natural selection shall be a confirmed explanatory mechanism in biology. This twofold way of thinking about selection originated in the work of the founding fathers of theoretical population

genetics—Ronald A. Fisher, John B. S. Haldane, and Sewall Wright—in the 1920s. They began to study mathematically the genetic base of natural selection and thereby made possible the modern synthesis of Darwinian evolutionary theory and Mendelian genetics.

Whether natural selection is really the principal mechanism responsible for the evolution of life on Earth is a highly debated question. Current criticism often aims at some tendencies in orthodox Darwinism to turn natural selection into an almighty power. Research on molecular evolution has shown that most genetically transmitted mutations are selectively neutral, so that random genetic drift of such neutral mutations constitutes another important mechanism effective in real evolution (Motoo Kimura). Other critics underline the importance of nonadaptive phenotypic properties of organisms, which have to be seen either as features necessary for the stability of their anatomical structure or as vestiges of formerly functional adaptations (Stephen Jay Gould).

SEMANTICS, ETHNOGRAPHIC

Ethnographic semantics, also called “ethnoscience” or “the new ethnography,” is a methodology for formally uncovering how certain parts of culture are talked about—and presumably thought about—by native participants. It developed in the 1960s—mostly in the United States—as a branch of the newly named subdiscipline of cognitive anthropology (itself part of the general reaction to behaviorist paradigms in psychology and linguistics held through the 1950s).

Some equated ethnographic semantics with cognitive anthropology, though the latter term is now more closely associated with the discipline of cognitive science.

Several things prompted the rise of ethnographic semantics. First, even before the notorious Mead-Freeman controversy that erupted several decades later, it was becoming increasingly clear that different anthropologists were concluding different things from work at the same field site. In other words, ethnographic reliability and replicability were being questioned. Second, anthropologists were becoming more sensitive to issues of language and cultural knowledge. In short, anthropology was developing a renewed interest in covert meanings as opposed to overt structures. But while it was clear that language and culture were rule-bound—and that natives knew the rules well—most natives were hard-pressed to explain them. What was desired was a methodology that would address both these problems.

But if more attention was now being focused on systems of ideas, the question remained as to how they might best be retrieved. Simple ethnographic interviews would clarify the particulars of specific cases (assuming an ethnographer knew how to ask the right questions), but this would not necessarily capture the organization and structure of knowledge that informants had of their culture. Some kinds of formal devices were needed to extract this information in a rigorous, consistent, and reliable way. Two of the most favored were taxonomies and componential analysis.

In doing a folk taxonomy, the goal was to uncover how some domain—a labeled category of some aspect of culture—was hierarchically ordered. Such a structure was thought to reflect in many key ways how the people in a language-culture conceived of this named part of the universe. As a simplistic example, let's say the proverbial Martian anthropologist comes to Earth and wants to know how Americans think about furniture. In the native language he will ask an informant to "Tell me all the words you have for FURNITURE." This ideally gives all the items in this domain. Then the anthropologist attempts to tease out how all these words are organized by using other key sentences like "Is X a kind of Y?" After several iterations, structures will emerge (e.g., finding "kitchen tables" and "end tables" are a kind of "table," but not a kind of "desk"). In a

componential analysis, the key attributes that make up a term are explored (e.g., in the English kinship system "father" being [+male], [+consanguine], [+1 generation above ego]). In both techniques, if the formal elicitation frames are conducted properly this supposedly assures that similar results will be found no matter who conducts the research.

Ethnographic semantics has been applied to numerous domains in hundreds of cultures, including disease terms in American English, categories of beer in Germany, color-textures in the Philippines, and scores of plant and animal taxa. Proponents argue that taxonomies and componential analyses demonstrate many cross-cultural similarities, and provide a universal framework for the study of native vocabulary. However, it now appears that human classification is much more complex than the original ethnoscientists envisioned, and ethnographic semantics is used more often today to supplement rather than replace standard ethnographic techniques.

SERVICE, ELMAN R. (1915–1996)

Elman R. Service, a prominent cultural anthropologist of the 20th century, was born May 18, 1915 in Tecumseh, Michigan. His theory of cultural evolution that occurs as organic and superorganic factors influence different types of social organization in small-scale society is prominent among anthropologists, ethnologists, and social anthropologists.

Service completed his undergraduate degree in anthropology at the University of Michigan (1941) after serving in the Abraham Lincoln Brigade to fight fascism in Spain, which spurred his interest in

anthropology, and he completed his PhD in anthropology at Columbia University (1951). He served on the faculties of Columbia (1949–1953), the University of Michigan (1953–1968), and the University of California at Santa Barbara (1968–1985). He was married to Helen S. Service and remained involved in anthropology at Santa Barbara until his death on November 14, 1996. He was a member of the American Anthropological Association and the American Ethnological Society.

Attracted by the cultural dynamics of Latin American Indian ethnology, Service conducted field research in Paraguay, Mexico, and among the Havasupai culture of the Grand Canyon. Utilizing sophisticated ethnological research methodologies, which he developed throughout his distinguished career, Service conducted field research throughout Latin America focusing on cultural evolution and decision making among Indian peoples, discovering the organic (technological) and superorganic (cultural) circumstances and configurations that produced different types of social organization prior to the state.

Service developed a typology of societies whereby most societies can be classified into four principal types of social order (political organization and other social characteristics): bands, tribes, chiefdoms, and states. Applying trend analysis, he classified levels of political integration, specializations of political officials, modes of subsistence, community size and population density, social differentiation, and forms of distribution.

Based on the level of social order or organization, Service deduced that most societies had evolved to the state type, characterized by multilocal group political integration, high degree of specialization of political officials, an intensive agriculture and herding mode of subsistence, urban with high density of population, a class form of social differentiation, and a market exchange form of distribution.

Service's theory of cultural evolution is that the state, an institutionalized structure of authority, is virtually nonexistent in hunter-gatherer groups, where leadership positions are rarely permanent, and develops in agrarian society, where organizations and institutions are more likely to become integrated with stable configurations at each technological or cultural level, especially when stability has existed for a long time. Thus, he concluded that if no clearly definable organization tends to exist, there is no

organization, suggesting that there may be cultural systems where redistribution could take place without one person being consistently the key to its workings.

SEX IDENTITY

Sex identity refers to the social criteria by which men and women are defined within society. Although physical sex is biologically determined, sex identity, or gender, is defined culturally. There is thus variation in how women and men worldwide identify themselves with respect to each other.

The way in which a society defines sex identity is based on its cultural framework. Cultural definitions of sex identity are linked with a society's sex roles, which are in turn connected with the society's subsistence pattern, economic structure, kinship system, religious system, and so forth. Cultural ideas about sex identity therefore define ideal identities for women and for men and provide mechanisms by which individuals can live up to those ideals.

Identity and roles are related to the extent that specific roles are often a component of identity. Therefore, although sex identity is ascribed, meaning that it is given to an individual by society, it is also partly achieved by an individual through the fulfillment of the social roles that correspond to his or her identity. For example, primary sex roles include reproductive and productive roles. Where these sex roles are integral components of sex identity, failing to procreate or to perform the subsistence tasks associated with one's sex may lead to social stigma and doubts concerning an individual's true identity as male or female.

Other aspects of identity include general disposition and behavior. It is often the case that particular personality traits and their expression in specific socially defined ways contribute to an individual's perceived sex identity. Since a major aspect of sex identity concerns one's relationship with the opposite sex, male and female sex identities are often constructed in opposition to each other. Therefore, the personality traits, behaviors, and dress code that are considered appropriate to each sex are frequently in binary opposition to each other.

While this opposition of male and female identities is a human universal, societies differ in the extent of overlap between the two identities. While some cultural schemes delineate strict divisions between female and male identities so that they symbolize discrete categories, others have a large number of roles and behavioral traits that are considered to be characteristic of both sexes, with a few traits that are used as barometers of masculinity and femininity.

The opposition between female and male is mediated by alternate genders in many societies, particularly in North America. Societies such as the Navajo and the Mohave recognize that it is possible to assume a sex identity that does not correspond to one's sex at birth. For example, a biological male may assume the sex identity of a woman by taking on female chores, behavior, and dress.

People learn their sex identity from their parents and other members of their society through enculturation, the process whereby cultural values, practices, and meanings are instilled in an individual. This is done through various means such as verbal instruction, observation, and imitation, and the use of corrective measures in cases of inappropriate behavior. These measures aim to encourage the individual to adhere as closely as possible to the cultural ideal of what is masculine or feminine.

A primary means by which people achieve their sex identity is through initiation rites that mark the passage into adulthood. These rites are usually performed in adolescence and are designed to enforce adherence to characteristics of the appropriate sex identity and to teach youths how to fulfill their eventual roles.

It is therefore during initiation rites that youths prove that they are able to fulfill adult roles and to live up to their society's standards for female or male identity. For example, initiation rites may stress the ability to endure pain. In the case of the Kpelle

of Liberia, male initiates are separated from their community for several years and made to endure circumcision and scarification as well as general harsh treatment. Throughout this period, they learn various tasks associated with men's work.

On the other hand, a girl's first menses may prompt the arrangement of a ceremony where themes that are central to women's lives are stressed. Among the Apache of North America, for instance, a girl's puberty ceremony invokes aspects of fertility and motherhood. Through various phases of the ceremony, allusions are made to Changing Woman, an Apache deity that symbolizes fertility and female strength.

Regardless of the form it takes, sex identity is an integral part of individual identity in most societies. Since it is learned from early childhood onward and is continually reinforced through various social mechanisms, this component of identity is often perceived to be normal and natural to the members of a given society.

SEX ROLES

The term "sex roles" broadly refers to the various social functions that are ascribed to individuals based on their physical sex. Sex roles are one category of roles among other social roles that are developed in societies to regulate human behavior and relationships.

One major aspect of human existence that contributes to the formation of sex roles is a person's reproductive potential, which is directly related to his

or her physical sex. In all societies, it is women who give birth to children and in many societies, it is women who exclusively feed them for the first few years of their lives because of their capacity for breastfeeding. Men's major contribution to the reproductive process is to inseminate women. Societies vary with respect to a biological father's implication in childrearing.

Sex roles in a society are also highly related to its subsistence pattern, or the means whereby food is obtained or produced. Depending on subsistence activities, there is a different sexual division of labor, or pattern whereby women and men divide subsistence tasks. Women tend to engage in tasks that are compatible with breastfeeding and other childcare activities whereas men tend to be assigned tasks that require travel further from the household. As with other human tendencies, however, there are exceptions to this pattern and there is wide variation with respect to which tasks are appropriate for men and women.

One common example of sex roles connected to the sexual division of labor is found among many foraging societies: men hunt large game and women and children gather wild plant foods and small game. In many cases, such as among the Ju/'Hoansi of Africa, women contribute a large portion of the diet, but men provide most of the highly prized meat. In a few societies, women contribute to the acquisition of meat either by hunting on their own, as is the case with the Agta of the Philippines, or by participating in communal hunts with men and children, as is the case with the Mbuti of Africa.

Agricultural societies, where subsistence depends on intensive cultivation, also vary with respect to the sexual division of labor. The tasks of women in these societies can range from processing harvested crops and tending farm animals, both of which can be performed close to the homestead, to active participation in plowing fields and other physically demanding tasks.

Superimposed on the division of labor in any given society are cultural beliefs about the relative importance of tasks assigned to men and women, the relative value of what is produced by these tasks, and the relative status of men and women. In some cases, men's work may be more highly valued because of the scarcity of that which is obtained, such as meat. This is often connected to higher social status for men. However, while higher status may entail a greater

control over resources and their distribution, it may or may not entail greater power over women and their activities. Indeed, there is a wide range of variation with respect to power relations between women and men.

Sex roles are therefore also connected to political roles. Societies vary in the extent to which women participate in community decision-making processes. Societies that are egalitarian in nature tend to include women in decision-making processes, whereas more hierarchical societies tend to place most of the power in the hands of men.

In the earlier part of the 20th century, most Western societies subscribed to a model whereby women's roles were limited to bearing and rearing children and to household tasks. There was, therefore, an assumption that it was natural for men to be the primary breadwinners and decision makers. However, the anthropological record shows us that there is a great deal of variation in the way men and women contribute to the survival of their families and societies and in the way social control is exercised.

SEXUAL HARASSMENT

Sexual harassment is the act of using some element of power to solicit a sexual favor from a person who does not want to participate in a particular activity. It is unwelcome activity in the form of speech, print, gesture, or some other form of sexual communication. Such activity is harmful and illegal and may result in adverse psychological, economic, emotional, and even physical effects on a person. We seem to

hear and read more about sexual harassment when it occurs in a private work environment, yet it has been shown to be a common occurrence in other arenas such as educational establishments, the military, and other public institutions.

Typically, sexual harassment involves a male harassing a female who is subordinate in the relationship. However, a male can be the victim of sexual harassment as a result of a female's behavior, and sexual harassment may also involve two individuals of the same sex. To decrease the incidence of sexual harassment, companies should adopt a clear policy that communicates to employees that sexual harassment is not permitted in their environment and that it will not be tolerated by anyone. We can expect the topic of sexual harassment to continue to be a major concern in our society, for a number of obvious reasons. For example, the role of women in the world is changing. They are more likely to be found in key positions in all walks of life where their presence is important and influential. In addition, they are more educated and more attuned to the need to work for equal treatment, which is something they deserve as major contributors in society.

SEXUAL SELECTION

Sexual selection operates under the same process of differential reproductive success described by Darwin in *The Origin of Species*. This success, or fitness, is determined by the amount of genes contributed by an individual to the next generation. Sexual reproduction adds genetic variation and allows for distinct sets of characteristics, some of which are advantageous and allow for the perpetuation of specific traits.

Natural selection drives population change. Sexual selection is the mode by which an individual chooses a mate with specific traits and behaviors.

The goal of any individual is to produce viable offspring, so he or she will select a mate who can ensure the achievement of this goal. Among many other species, mate selection is determined by female choice based on male display. Attributes such as a lion's mane or a peacock's tail feathers attract attention and lure partners. However, there are other species, like the Emperor Penguin, that have comparable nurturing responsibilities. Because the male and female take turns with the task of incubating an egg, both sexes are active in the selection process. In comparison, the male seahorse is the main contributor in ensuring the survival of the fertilized eggs. In short, the sex that expends more energy to guarantee reproductive success holds the power of choice.

In humans, sexual selection is based on both biological and cultural factors. Biologically, pheromones, chemical odors produced by the body, can attract potential mates. First discovered in silkworms in 1956, pheromones produce physiological responses and affect interaction. German researchers were able to isolate and extract a chemical compound from the female moth that resulted in the male moths beating their wings in a "flutter dance" without the presence of the actual female. Furthermore, a 1971 study of women in a college dorm showed that human pheromones influence menstrual cycles by synchronizing them. This sexual chemistry is also seen in the high levels of hormones released during initial attraction, which have similar properties to amphetamines and act to heighten awareness. On the other hand, endorphins, which create a euphoric sensation, are released in the presence of long-term partners.

Cultural factors that influence courtship rituals include concepts of beauty and social status. Universally, each culture has certain attributes that are desired in a mate, the three most important being health, age, and body symmetry. However, in the concept of health, what is defined as healthy is culturally determined. For example, a female considered overweight and unattractive by North American standards may have the ideal proportions in Latin America. Cross-culturally, however, men are more likely to place higher value on physical attractiveness, whereas women focus more on personality and social status.

Attraction, whether physically or socially determined, allows individuals to pick the best possible

candidate for both reproduction and childrearing. Even though many cultures permit polygamous relationships, few individuals are wealthy enough to put this custom into practice. Because of the long infant dependency of humans, both partners must expend energy to care for the young; therefore, monogamy is a more common cultural practice. However, this evolved from a more general trend of serial pair bonding, in which individuals had only one partner at a time but more than one throughout life.

For humans, though, sex is not only about reproduction. Sexual interaction is also associated with play, intimacy, and emotional attachment and comes in many different forms. Sexual practices vary cross-culturally and are directed by learned behaviors.

SEXUALITY

Human sexuality holds a great interest for anthropologists. As a biological reality and a reproductive force, sexuality affects all humans. However, there is much diversity in the experience, expression, and interpretation of sexuality throughout the world. Using a holistic perspective, meaning that various aspects of the human experience are considered to be interrelated and interdependent, anthropologists consider biological as well as cultural factors in an attempt to understand and explain the dynamics of human sexuality.

Some anthropologists are particularly interested in the interrelationship between sexuality and human physical and cultural evolution. Physical changes in the human species over time have influenced the nature of sexuality. In turn, changes in sexual practices may

have had an impact on the physical changes that humans have undergone.

If sexuality is a biological reality, it is nevertheless interpreted through the various cultural frameworks in which it is experienced. Therefore, human culture has an enormous impact on the diverse meanings attributed to sexuality and sexual behaviors. Anthropologists consider sexuality to be a central aspect of human social organization that influences, and is influenced by, various other aspects of society such as food-getting, family structure, and religious belief.

Human Evolution and Sexuality

While all mammals, including humans, reproduce sexually, humans exhibit different patterns of sexuality than other members of this class of animals. Even among the primates—the order in which humans are categorized in the Linnaean taxonomic system and that includes apes and monkeys—humans are distinct when it comes to patterns of sexuality.

These differences are considered by anthropologists and other scientists as being representative of adaptive strategies, or coping mechanisms, that humans have adopted over time in response to environmental, biological, and social pressures. While some scholars focus on these pressures individually, the discipline of anthropology generally acknowledges that they are likely to be interconnected. In other words, there may not be one individual source for the uniqueness of human sexuality.

In contrast to many other mammals, for example, human females are sexually receptive throughout the year, regardless of whether or not they are fertile. This characteristic is related to the loss of estrus among human females. That is, at some point in their evolutionary history, human females gained the physical capacity to conceal ovulation. The period of time during which females are fertile became unknown to males and, in most cases, to females themselves. The process whereby females gained concealed ovulation may be linked to other physical changes that occurred through evolution such as the ability to walk upright and the loss of body hair.

As a byproduct of this change, humans mate throughout the year and sexuality has implications that range further than its reproductive function. The social impact of this trait touches on marriage, family structure, economic structure, and so forth. A related

trait, for instance, and another distinction between humans and many other mammals, is that humans demonstrate a tendency for pair bonding, where a male and a female collaborate in the raising of offspring.

What is the adaptive advantage of these interrelated traits? One answer may be that since humans have a longer gestational period and offspring have a longer maturation period than those of other mammals, collaborative parenting may lead to a higher success rate in the raising of young. Human babies are born defenseless and unable to survive on their own. Parents must therefore feed and shelter their young for a longer period of time. The capacity for year-round mating may be one factor that facilitates the maintenance of these pair bonds since the male and the female mate repeatedly, even during times where there is no possibility for reproduction.

Another example of the correlation between physical changes and human sexuality is sexual selection. Sexual selection refers to the process whereby physical traits that are highly appealing to members of the opposite sex will give the carrier a higher chance of obtaining mating partners and of passing on his or her genetic material to the following generation. Along with natural selection, where individuals with traits that help them survive stand a better chance of living long enough to reproduce and pass on the genes for those traits to the following generation, sexual selection is considered by anthropologists to be an important factor in the genetic variation of the world's human population.

Some scientists claim to have found traits that are universally considered to be appealing, such as body symmetry and the appearance of good health. This might lead anthropologists to conclude that humans are predisposed to desire certain traits in sexual partners. However, culture plays a vital role in this process as well. Cultural ideals about beauty in males and females play a large role in what is considered appealing or what is considered to be a sign of good health. Within a society, these ideals may change over time.

Culture and Sexuality

For humans, sexuality is more than a reproductive force. Humans engage in sexuality for pleasure, love, or other reasons. These reasons may supplement, or even replace, the desire to produce offspring. Nevertheless, the reproductive potential of sexual

relations, particularly in the case of opposite-sex relations, affects the ways in which sexuality is experienced, even when it is performed for other reasons. At the social and cultural level, sexuality encompasses a wide range of human experiences, from sexual relations themselves to individual roles and identity.

The cultural experience of human sexuality is quite diverse and varies alongside myriad factors that stem from local cultural adaptations. These factors include subsistence patterns, kinship systems, and worldview. Therefore, while sexuality is a universal phenomenon, there is variation with regards to its actual functions within specific cultural contexts.

A society's subsistence pattern, or how societies obtain and distribute essential resources, may influence sexuality by providing a context to which people must adapt to survive. Subsistence patterns such as foraging, where people obtain their resources by hunting wild game and gathering wild plant foods, or agriculture, where people grow crops on permanent plots of land, entail different kinds of divisions of labor between men and women. In most cases, women will take on tasks that are amenable to their capacities for bearing and nursing children. There are exceptions to these patterns; societies vary in their flexibility toward the types of work that men and women perform.

This sexual division of labor has implications for a society's kinship system, or how societies regulate marriage and family structure. If tasks and resources must be managed for the survival of the group, social relations, including sexual relations, must be managed to avoid social conflict due to sexual tensions and jealousy and to provide a framework within which resources are shared.

Marriage, a human universal, is a means whereby sexual relations are sanctioned and recognized within a society. This institution takes different forms, however. Marriage can be monogamous, taking place between two individuals, or polygamous, meaning that one individual may have more than one spouse. There are two types of polygamy: polygyny, the more common form, permits a man to have two or more wives, whereas polyandry allows for a woman to have two or more husbands. Monogamous marriages are the statistical norm throughout human societies. However, many societies place a high value on polygamy as an ideal form of marriage. Regardless of the form it takes, marriage involves mutual responsibilities among spouses, including sexual obligations.

In fact, failure to meet sexual obligations is grounds for divorce in some societies.

Across the ethnographic spectrum, there is a range of expectations on sexual behavior before, during, and after marriage. These expectations are often different for males and females. In many cases, female virginity at marriage is highly prized and is a reflection of family honor. On the other hand, societies such as the Canela of the Amazon allow teens of both sexes to engage in sexual experimentation before marriage and encourage extramarital sex. Finally, there exist, in some cases, taboos against sex after the death of a spouse, particularly in the case of widows.

While traditional anthropological literature referred to marriage as a union between at least one man and one woman, same-sex unions that meet the criteria for the anthropological definition of marriage exist. In some African societies, such as the Nuer and the Zande, same-sex unions of varying levels of formality occurred. Today, same-sex marriages are being legally recognized in some Western nations such as Belgium, the Netherlands, and Canada.

Another human universal that is related to kinship is the incest taboo. In all societies, sexual relations or marriage are forbidden between people who are considered to be closely related. The degree of closeness is culturally determined. In most cases, forbidden sexual partners include parents, grandparents, siblings, and children. Certain categories of cousins, aunts, and uncles are frequently included. Depending on the kinship system, other individuals may be off limits because of their names or other culturally defined parameters.

There are various theories that explain the existence of the incest taboo. One concerns congenital problems that may arise through inbreeding. Another explanation is the “aversion theory,” which postulates that children growing up together, such as brothers and sisters, will develop a sexual aversion to each other. Finally, the “alliance theory” states that it is advantageous for any group to form alliances with other groups. Marriage outside the immediate family establishes and maintains social ties between groups and provides a wider network of people upon which a family may draw in times of need or conflict.

If subsistence patterns and kinship systems help explain the practicality of certain sexual patterns, worldviews give meaning to sexuality. A worldview is a set of ideas that explain the world and prescribe appropriate behavior. An example of a worldview is

religion, or a set of beliefs and practices regarding the human connection with divine or supernatural forces.

Regulations on sexual behavior that may appear to an outsider to be simple adaptations to local realities or arbitrary sanctions may carry greater significance to members of a society because of a shared worldview. Practices such as same-sex relationships, masturbation, oral sex, anal sex, sex during menstruation, sequential sex, group sex, spouse exchange, use of pornography, prostitution, and sexual violence are prescribed, prohibited, or relegated to particular circumstances according to beliefs and assumptions about what is appropriate and normal sexual conduct.

In fact, some acts that would be considered to be sexual in nature by Western standards are not considered sexual at all in their respective cultural contexts. For example, anthropological informants in African societies such as the Lesotho of South Africa have indicated that sex is defined by the contact between a penis and a vulva. Therefore, genital contact between members of the same sex is not considered to be sex.

While norms exist in every culture regarding sexual behavior, these norms represent a cultural ideal. In practice, there is variance from the norms in some individuals. Societies differ in the manner in which individuals believed to have transgressed sexual norms are treated. Sanctions may range from divorce, as in many Western societies in cases of adultery, to social stigma, as in the case of a Canela individual who refuses sexual access to another, to corporal punishment, as in cases of homosexuals who are persecuted in nations where homosexual activity is illegal.

Positions for intercourse are also socially prescribed and are often tied in with beliefs about what is normal or natural. While it is extremely difficult to observe sexual intercourse given the human tendency to conduct sexual acts in private, ethnographers have collected data on the frequency of particular positions. The most common positions for heterosexual intercourse are the missionary position, with the man lying on top of the woman, woman-on-top, man and woman side by side and face to face, and rear entry, with the man penetrating the woman's vagina from behind. The desire for orgasm also varies from culture to culture according to beliefs about the nature and purpose of sexuality. These beliefs are often connected to ideas about sex and gender identity, beliefs about the process of reproduction, or the relative social positions of males and females.

Through ethnographic studies, social and cultural anthropologists have found that there exists a great

diversity with respect to the ways in which sexuality is discussed with children or among adults. From sex-positive societies such as the Trobriand Islanders and the Canela, where children have opportunities to observe adults engaging in sexual intercourse, to sex-negative societies such as that of Inis Beag, Ireland where sex was rarely mentioned and was the cause of great anguish, there exist many patterns of ideas and practices.

Human sexuality is a complex subject but it is crucial to an understanding of the human experience. Today, as in the past, conflicts arise between and within societies regarding the appropriateness of various forms of sexual conduct, the roles of the sexes, and so forth. Since one's society so strongly influences an individual's perception of what is normal and natural sexual behavior, it can be difficult to accept the sexual practices of an unfamiliar culture. Unbiased anthropological inquiries into the evolution of human sexuality and the diversity of sexual norms and practices may help to shed light on these conflicts. However, since sexuality is such a central part of human life and touches on core aspects of group and individual identity, it is impossible to predict whether these conflicts will ever be resolved.

The shaman is a ritual specialist who is a healer and spiritual mediator. He or she entertains a close relationship with the larger spiritual universe, endowing him or her with powers to divine or to heal and act as a psychopomp—a guide of the souls of the deceased

to their afterlife. The word shaman is derived from the verb *šaman* meaning “to know.” The term was borrowed from the Manchu-Tungus languages (comprised of, among others, the languages of the Even and the Evenki peoples of the Russian Far East and northern China). Shamanism is a powerful vocation, at times hereditary but always achieved through demonstrated expertise in the shamanistic arts. Though the first descriptions of shamanism were recorded in the Russian Far East, anthropologists and others now use the term to describe an array of ritual and religious practices that are found across the planet.

The classic work that summarized and defined shamanism was Mircea Eliade's *Shamanism: Archaic Techniques of Ecstasy*. First published in French in 1951, this text provides a detailed account of shamanism in all its facets. Eliade's work highlights some of the characteristic features of shamanism, which include the initiation of the shaman, the powers of the shaman, and the shaman in traditional cosmology. The term shaman is, in many ways, synonymous with the term “medicine man” or “curer” that was often applied to comparable ritual specialists in the Americas and elsewhere.

Central to shamanism is the spiritual death and rebirth of the shaman. Among the Sakha (Yakut) of the Russian Far East, a great bird carries off the future shaman's soul to the underworld where it must ripen. Once ready, the bird carries the soul back to the earth where it is cut into pieces and devoured by spirits of disease and death. It is through the feasting that the shaman gains power over these spirits, and the greater the number of spirits partaking in the feast, the greater the powers of the future shaman. In other regions, the shaman is spiritually tortured and killed by the souls of shaman ancestors who also cook the flesh. While the spirit is being devoured, the physical body of the shaman remains inert, and the community waits for the rebirth of the shaman. Shamans do not always willingly accept the “call” of the spirits or ancestors: in certain cases, future shamans will become physically ill and incapacitated if they resist the call to the vocation.

Once reborn as shaman, the new initiate must master shamanic techniques including songs, ritual techniques, and knowledge of medicinal plants. The shaman's assemblage often includes a drum or other musical instruments. The shaman is seen as having the power to communicate with spirits and the

Source: © MagnumPhotos.

shaman's spirit can often travel to distant locations, often the upper or lower spirit world. Central to the practice of the shaman is the altered state of consciousness or psychosomatic trance, in which the individual enters into a highly charged emotional state and is carried beyond normal consciousness and rationality. Though hallucinogenic plants are sometimes used to achieve this altered state, the shaman can achieve this state through the use of rhythmic sound and movement, thus the importance of the drum that can mimic the rhythm of the beating heart. However, achieving an altered state of consciousness is not the end; rather, it is simply the means to the end. The purpose of the ceremony and the ritual is to permit shamans to channel their souls and spirit-helpers to communicate and interact with the supernatural universe, exercising their power over the spiritual domain.

Elements of shamanism are found across the globe and in a number of forms of religious belief. Though shamanism is associated with animism, shamanic elements are found in Buddhism—the lama in Tibetan Buddhism is in many ways a syncretism of shamanic and monastic practices; Islam—the Whirling Dervishes use music, rhythmic prayer, and chants as well as dance to achieve a form of trance; and certain Christian sects that believe they can be possessed by the Holy Spirit and speak in tongues. However, those individuals that we can truly identify as shamans are usually found in those societies in which humans

are part of a much richer spiritual tapestry, as is the case in the Russian Far East and Northern Asia.

Central to shamanistic cosmology is the division of the cosmological universe into an upper, middle, and a lower world inhabited by a variety of sacred entities and spirits. Shamans draw their power from the ability to navigate between these layers. In Central and Northern Asia, at the center of cosmology is the “World Tree,” the tree of life and immortality; in other regions it is a “World Pillar” or a “World

Mountain.” The tree, pillar, or mountain is rooted in the underworld, tying it to the sky; it can also represent the many layers of the sky, and only the most powerful of shamans can ascend to the very apex of the heavens.

Symbolism and ritual are central to the practice of the shaman. The drum and other accoutrements of the shaman are usually decorated with a world tree or other elements of cosmology. The drum and instruments are the sole preserve of the shaman and retain the power of the shaman after death; after death a shaman's drum is often cut and rendered unusable, and the shaman's spirit is treated with due care. The same is true of the costume—often decorated with mirrors, pieces of metal, and a variety of symbols and patterns, it is a cosmological microcosm, inhabited by spirits even after the death of the shaman. In certain regions, the shaman dons a mask as part of his costume.

Shamans play a variety of roles. In certain societies, shamans can be either “white” or “black” as some will use spirits to harm rather than to help humans. The shaman is often called upon to diagnose the cause of misfortune that may be plaguing a community—for example, a long spell during which no game is killed while hunting. Under these circumstances, the shaman will try to identify any taboos that were broken or other breaches that may have offended or disrupted the spiritual harmony. Shamans invariably are called upon when illness strikes. Often disease is

understood in spiritual terms, caused by either spirits that attack or inhabit the body, or the loss or theft of one's soul (for example, by a sorcerer or rival shaman in another village), and shamans are called upon in these circumstances to diagnose the cause of illness and to use their powers to redress the spiritual imbalance and bring about a recovery.

SHANIDAR CAVE

Shanidar cave is located in northern Iraq at an altitude of 745 m. Nearby is the village of Zawi Chemi Shanidar, with archaeological remains dating back to ca. 10,000 BC). However, Shanidar is known for its middle-Paleolithic remains, which include several Neandertal skeletons between 60,000 and 46,000 years old.

The cave was first discovered by Ralf S. Solecki and T. Dale Stewart and was excavated from 1953 to 1960. During the first excavation, a complete skeleton of a nine-month-old child was found (Shanidar 9). It was difficult to know that he was a Neandertal because the bones were severely deformed. Later this individual would be studied by Muzzafir Senyürek from the Smithsonian Institution. This was the first of a total of nine individuals (two infants and seven adults) to be found during the excavations.

Shanidar 1 was about 40 years old when he died. He is a male who suffered a number of pathologies prior to his death; his right arm and leg were withered, and he had healed injuries to his right foot and left eye. Probably without the care of the group, this man would have died.

Shanidar 2 and 3 were found in 1957. They are respectively a Neandertal cranium and an almost complete skeleton of an adult male with a marked lumbar bilateral arthroses.

The Shanidar 4 skeleton was found surrounded by flowers considered to be of medical interest, which some researchers think were placed there intentionally. The palynological analyses showed that all the taxa represented had therapeutic properties.

Together with Shanidar 1, 3, and 4, Shanidar 5 shows signs of injuries ante mortem. Specifically, this adult had a wound over his left frontal. This individual was found in 1960 along with parts of Shanidar 4, 6, 8, and 9. Shanidar 6 and 7 were found beside Shanidar 4, and finally, Shanidar 8 was a little child.

The study of these Neandertal remains, together with those from other locations, shows that although it is common to find a high number of injuries, there was a strong feeling of cohesion between group members, which permitted the survival of the weak individuals.

SIAMANGS

Siamangs are members of the order Primates belonging to the “lesser ape” family or Hylobatidae. Their scientific name is *Hylobates syndactylus*, although up until 1972 it was *Symphylangus syndactylus*. Siamangs are the largest species in the gibbon family, with a height of 30–35 inches and a weight of around 18–35 pounds. Siamangs have long black hair and a chromosomal count of 52. Most of the other gibbons have

Source: Photograph courtesy of Gregory Scott Hamilton, Honolulu Zoo.

chromosomal counts of 38 and 44, although one subgenus does have 52 chromosomes also. Siamangs differ from other members of their family by having a unique webbing of the skin between their second and third toes. There are two subspecies of siamangs, the Sumatran siamang (*H. s. syndactylus*), which is only found on the Indonesian island of Sumatra, and the Malaysian siamang (*H. s. continentis*), which is only found on the Malay Peninsula.

Siamangs mostly live in primary and some secondary forests. Their habitat ranges from lowland to mountainous forests, up to elevations of 12,468 feet. The majority of the siamang diet consists of leaves but also includes some fruits and flowers. Siamangs also have been known to prey on small animals. Siamangs spend the majority of their time feeding in the mid-canopy where common trees and leaves are abundant. They also feed at the tops of canopies and under cover near the ground. Members of a family group feed close together, usually staying within 100 to 200 feet of one another. Siamangs typically have smaller day and home ranges than other gibbon species due to the abundance of available leaves in their diet.

Like all hylobatids, siamangs live in monogamous families consisting of one female, one male, and offspring. Siamangs have a gestation period of 200–239 days, and females give birth every two to three years.

During the first year, siamangs spend most of their time with their mother, but during the second year they spend more time with their father. The offspring stay with their parents for up to nine years. When the juveniles become young adults, they leave their parents to start their own families.

Siamangs are an arboreal species and rarely walk on the ground. They brachiate using their long arms and long, skinny fingers. Siamang hands are cup-shaped, allowing them to swing freely through the trees without having to grasp firmly onto branches.

Siamangs also locomote bipedally along tree branches, holding their arms in the air so they do not drag on substrates. All gibbons, including siamangs, are renowned for their great vocal calls. Siamangs, however, have the most powerful call of all. They have an enlarged vocal sac in which vocalizations reverberate, making them extremely loud. Every day, the male and female duet together in 20-second bouts that can continue for 15 minutes at a time. Like all species of gibbons, siamangs are threatened by habitat destruction on both Sumatra and the Malay Peninsula. In fact, both species of siamang are endangered.

Siberia is the continental region of north Asia; located in the Russian Federation, it extends from the Ural Mountains to the Pacific Ocean. Noted for its unforgiving climate and expansive boreal forests, or *taiga*, Siberia has contributed much to ethnological research, including studies of its indigenous peoples and languages, shamanism, and processes surrounding Russian colonization. Having been inhabited since the Pleistocene, Siberia is important to comparative research in old world prehistory and Paleolithic ecology. Research in Siberia today is integral to the anthropological study of Eurasia as it undergoes political and economic change after socialism.

Research on Siberia significant to anthropology includes a great deal of work on the history and ethnography of its native peoples. The history of Russian interaction with native peoples of Siberia, including the rapid expansion of the Russian Empire and its tribute and administrative systems, has been an important topic in comparative political economy and world systems theory. Studies of Siberian kinship and shamanism have influenced ethnological theories of social organization and religion. Soviet anthropologists had their own theoretical and applied developments relating to Siberia that flourished under the Marxist-Leninist prerequisites of the Soviet Union. Anthropological research in the circumpolar region, Beringia, and theories on the peopling of the New World involve Siberia. Property and identity transformations in Siberia have spawned a rich collection of ethnographic research in Eurasia since the 1991 cessation of the USSR. The documentation of endangered languages and practices of Siberia is an important area of applied anthropological research.

Archaeological studies have shown early peoples inhabited Siberia at least 20,000 to 8,000 years before present. Wide areas of the Eurasian Arctic coastline inhabited earlier are now submerged, including Beringia, the “land bridge” to North America. Anthropologists have made comparisons between the northwest coast of North America and the northeast coast of Asia that show striking ethnographic commonalities. Human interactions with big game, such as mammoths and other ungulates like reindeer and caribou, in Siberia and the New World are an important focus for paleoecological and human-rangifer comparisons across the circumpolar zone.

Modern ethnographic investigations of Siberia began under the direction of Russian anthropologists who published in Russian and English. Waldemar G. Bogoras (1865–1936) conducted ethnographic research with the Chukchee, Siberian Eskimo, Koryak, and Yukagir. One of his most influential studies, *The Chukchee*, was published in the Jesup North Pacific Expedition series edited by Franz Boas. A contemporary of Bogoras, Lev Iakovlevich Shternberg (1861–1927) worked in southeast Siberia with the Gilyak, Orochi, Goldi, Negedals, and Ainu. Shternberg’s ethnography on the social organization and sexual life of the Gilyak influenced Claude Lévi-Strauss’s thinking on kinship and marriage. Waldemar Jochelson (1855–1937), a contemporary of Bogoras and Shternberg, worked with Aleuts, Kamchadals, Koryak, Yakuts, and Yukagir. Jochelson’s *Peoples of Asiatic Russia* was published in 1928 by the American Museum of Natural History. Bogoras established ethnography as a discipline in Russia and the Soviet Union with his colleague Shternberg. After the revolution, Jochelson emigrated to New York. Sergei Mikhailovich Shirokogorov (1887–1939), another Bolshevik refugee working in northern China and southern Siberia, published influential studies on the *Social Organization of the Northern Tungus* (1929) and the *Psychomental Complex of the Tungus* (1935), adding to anthropological interest in Siberian kinship and shamanism.

The role of the fur trade in the expansion of the Russian empire and development of the modern Russian state has been explored in historical and political economic studies. Sable pelts, the soft Siberian gold of the 16th through 18th centuries, drove Russian military and population expansion east to the Pacific Ocean. This was extended to Alaska and south to Fort Ross in northern California. In the 19th century, the fur trade diminished in importance as a source of income for the Tsar, but the production of pelts of fur-bearing animals has remained important for Siberian peoples and rural economies to this day.

The connections between Russian colonization and ethnic developments in Siberia have been explored by anthropology and history. After the Russian Tsar’s defeat of the Tatar Khanate in 1551, Cossack armies continued east, defeating the horse-mounted and socially ranked steppe peoples in southern Siberia, and reindeer-herding and hunting-and-fishing people in northern Siberia. Beginning in the 16th century, Russian tribute collection intensified sable, squirrel, and fox hunting by native peoples, as did the fur trade

Source: © iStockphoto/Sergey Pristyazhnyuk.

in colonial North America. Russian fur trappers, merchants, and Russian Orthodox missions moved into Siberia, followed by peasants and exiles. Siberia's native identities and ethnic groups formed within the colonial context as the antithesis of Russian identity. Alexander Pushkin referred to the "Tungus, still wild" in an 1836 poem, for example. The Tsar's representatives created clan territories in Siberia, administered by native kings. Count Mikhail Mikhailovich Speranskii (1772–1839), while in exile in Siberia, developed a classification scheme (settled, nomadic, wandering) to determine tax and tribute liability as part of his effort at codification of Russian law. The Speranskii reforms also authorized clan administrations and steppe councils for administering Siberian peoples. Russian authorities continued to create and authorize native identities through the Soviet period, and this has been a subject of intensive anthropological study.

Soviet government policy on minority indigenous peoples was part of a larger problem of nationality across the Soviet Union. After the revolution, Vladimir Il'ich Lenin (1870–1924) promoted the idea of national rights for minority ethnic groups, and many gave their political support. A typology of administrative units was developed depending on the population of the ethnic group and its level of ethnic consciousness.

After the establishment of Soviet power in Siberia in the late 1920s and 1930s, the smallest ethnic

groups, or small-numbering peoples of Siberia (*malochislennye narody*), were recognized in the titles of national and autonomous regions (*okrugsy*) located in the Siberian provinces and territories. Larger ethnic groups, such as Yakut (Sakha) and Buryat, were recognized as titular nationalities in a series of autonomous republics within the Russian Federation. Early on, state ethnographers played critical roles in designing nomadic and clan soviets, as well as in determining favorable locations for planned cultural stations that included trading posts, red tents (for

visiting political agitators), schools, and health clinics. Soviet anthropologists tracked the historical development of "ethnos" in Siberia through ethnographic research and demographic studies using tribute and census data. The concepts of "ethnic processes" and "ethnogenesis" were prevalent in Soviet anthropology. The *Peoples of Siberia*, edited by M. B. Levin and L. P. Potapov and published in English in 1964, presented the Soviet view on Siberian natives.

Siberian peoples are well known as practitioners of shamanism, due in part to early historical and anthropological research. The word shaman is derived from an Evenk word, *šamān*, and has come to be used as the technical term for the religious leaders of kinship-based religions. Anthropological traditions in Siberian shamanism are strong among Hungarian, Russian, and American anthropologists. Siberian shamans are known to enter trances (*kamlanie*) during which they travel the cosmos to contact and influence spirits and deceased ancestors. Family and social rites were practiced, as well as rites to heal the sick and curse enemies. Siberian shamans were victimized as part of the political battle against primitive communism. Soviet policy toward shamans shifted through time and shamanism was viewed more in the line of folklore. Regional Departments of Culture created professional shamanic ensembles and recorded well-known shamans on the state Melodia

record label. Shamanism continues today in Siberia under new formats such as state licensing of shamans in Tuva and urban shamans in Buryatia.

Today, the 30 ethnic groups conforming to the small-numbering category have joined in a national association called the Russian Association of Indigenous Peoples of the North (www.raipon.org). The association, along with anthropologists and members of the international community, has been instrumental in lobbying for legislation promoting indigenous rights. A series of three laws was passed by the State Duma in 1999, 2000, and 2001 and signed into law, respectively, “on the fundamentals of legal status,” “on the organization of communes,” and “on territories of traditional nature-use” for “small-numbering native peoples of the North, Siberia, and the Far East.” Implementation of the laws has been uneven, and some regions have municipalized former state farm property and given small grants to individual entrepreneurs rather than support communes.

Industrial development occurred rapidly in Siberia during the Soviet era, especially when gulag exiles from European, Russian, and other Soviet republics were forced into hard labor during the purges. Native Siberians assisted operations in Soviet mining, metallurgy, and infrastructure by providing transport and through collective and state production of domestic and wild foods. Russian, British, and North American anthropologists have broadly pursued ethnographic study of the development of rural economies in Siberia since the early 1980s.

Indigenous peoples, having been incorporated into the state farms during the Soviet Union, had become increasingly dependent on outside sources of transportation, fuel, administration, health, and education. After the collapse of the USSR, the transition from the planned economy in Siberia has affected property relations, and this has been a major area of anthropological research. With the dismantling of Soviet agriculture, native Siberians were provided opportunities to form communes, or *obshchiny*, that could hold title to hunting lands and domestic reindeer herds. The success of these native organizations varies a lot, depending on the region and access to markets. Where access is better, Siberian *obshchiny* have been successful in entrepreneurial sales of traditional products such as meat, fish, and fur. Where access to markets is limited, Siberian hunters, fishermen, and herders have concentrated on subsistence production and common-pool resources. Many

traditional forms of knowledge and authority are being employed in hunting, redistribution, and consumption of native foods across Siberia in non-market social settings. Studies of hunting and gathering and subsistence in Siberia are important for understanding human adaptability and decision making in a rapidly changing mixed economy.

Archaeological studies on hunter-gatherer sites in Siberia are similarly important for understanding human involvement in the ecosystem, human migration, technological development, and climate change through time. For example, on Zhokov Island, 700 miles north of today’s Siberian coast, a hunting settlement dated at 8000 years BP is being excavated by a Russian and international team. The peopling of Siberia and North America is one emphasis in research that combines archaeology and geology in the study of human society.

Processes of domestication are another area of focus in the anthropology of Siberian peoples. Berthold Laufer, another Jesup Expedition anthropologist from Leipzig, Germany who worked on Sakhalin Island and the Lower Amur region, wrote an early theory on reindeer domestication. Outside of prehistory, interdisciplinary research in Siberia and the wider Arctic region has focused on relationships between people and domestic and wild reindeer. The human role in reindeer/caribou systems combines anthropological, biological, and native researchers in monitoring and local projects. This topic is but one that has developed with growing Arctic globalization—evidenced by growing regional contacts, scientific and economic exchanges, and treaties. Documentation of the native languages of Siberia is an area of applied research that can aid native peoples in maintaining language fluency in an era of rapid globalization.

 SICKLE-CELL ANEMIA

Sickle-cell anemia (Hb S) is an inherited autosomal (“non-sex” chromosomes) recessive blood disease that affects millions of people throughout the world. It is caused by a mutation in the gene for beta hemoglobin (an oxygen-carrying molecule), producing a change in the shape of the red blood cell into a sickle shape. The distorted shape of the red blood cell is unable to pass through capillaries and causes blood clots to form. Consequently, these blockages impede the flow of blood, causing hemorrhaging as red blood cells (RBCs) enter surrounding tissue, giving rise to many complications throughout the body.

The disease was first discovered in Chicago in 1910 by James B. Herrick, who described the anemia as “peculiar elongated sickle-shaped” red blood cells in a young black student from the West Indies. Many scholars acknowledge that even before Herrick, the awareness of African cultures with the disease was characterized by the intense and chronic pain of the disease. This explains the early name “Chwechwechwe” given to the disease, which was a description of the recurring pain experienced by the patient.

Physical anthropologists of antiquity used “racial admixture” and “Negro blood” to imply that there was an inherent difference between the black and white races. However, with time, as physicians continued to discover sickle-shaped cells in “white” individuals in different areas of the world, the focus on sickle-cell anemia as purely a racial disease was challenged. Numerous cases of sickled cells were soon discovered in “white” populations throughout the Mediterranean, Mexico, and Europe.

The sickle-cell disease affects millions of people all across the globe. In the United States, approximately 72,000 people are affected by the disease, with the disease occurring in 1 in 500 African American births and 1 in 1000–1400 Hispanic American births. There are approximately 2 million Americans and 1 in 12 African Americans who are carriers of the sickle-cell trait. In Africa, there is a large variance throughout, with 40% of some tribes having the disease.

It was in 1949 that physical chemist Linus Pauling found that the sickle-cell disease was due to a molecular defect in the hemoglobin molecule. It was a specific point in the molecular composition of hemoglobin that Pauling suggested caused the sickling of red

blood corpuscles. Molecular biologists determined that this disease was caused by an error in the amino acid substitution on hemoglobin. This was thought to be the first discovered molecular disease.

Molecular biology shows the importance of amino acid sequences during the formation of proteins. Each altered gene, called an allele, codes for different chemical and bonding interactions during protein formation. An individual who is homozygous for a gene has acquired two copies of one allele, SS (sickle-cell anemia) or AA (normal genotype). If only one sickle allele is inherited, then he or she is heterozygous (AS). In order for someone to have the sickle-cell disease, he or she must inherit the sickle-cell allele from both parents.

Scientists determined that if a child inherited only one copy of the Hb A allele from one parent then he or she was heterozygous and showed no serious health effects. It was also discovered that any individual possessing the sickle-cell trait would be resistant to malaria. Within populations, the advantages of having resistance to malaria are balanced through natural selection by the effects of sickle-cell anemia. Thus, although complex factors are involved, in areas where malaria is prevalent, the population will tend to shift toward selecting the sickle-cell gene for protection and to balance mortality. Biologists came to define this relationship of population genetics as “balanced polymorphism.”

The major symptoms of sickle-cell disease are joint and bone pain, rapid heart rate, decreased respiration and fatigue, ulcers on the lower legs, severe abdominal pain, jaundice, delayed growth, poor vision, and fever. The mortality rate of the sickle-cell disease is highest within the first year of life; therefore, early detection is necessary for increased survival. Doctors commonly use electrophoresis along with a complete blood count (CBC) to determine if Hb S is present. This simple blood test enables doctors to determine the presence of sickle hemoglobin in the patient. In addition, genetic counseling is recommended for all carriers to prevent or discuss the implications of having a child born with sickle-cell anemia.

Although no cure has been discovered for the sickle-cell disease, many new drugs and treatments have been developed to stop the factors that cause the recurring, painful sickling crises. Researchers have found that the inflammatory response causes the cells that line the blood vessels to be sticky. This leads to a build up of sickle cells sticking to endothelial

cells that line the blood vessels, eventually causing a blockage. Some studies have shown that anti-inflammatory drugs, such as steroids and ibuprofen, can relieve sickling crises. In addition, blood transfusions increase the red blood cell count, and regular transfusion therapy has been found to help prevent recurring strokes in infants.

The present research shows a promising future for patients with the sickle-cell disease. One future treatment may be in gene transplant, in which a virus is used to transplant a normal gene (hemoglobin A) into the bone marrow cells of a sickle-cell patient (hemoglobin S). Although the goal is for the gene to instruct the bone marrow to produce normal hemoglobin, it has not yet proven successful in humans. Additionally, new vaccines are being designed in hope of fighting infection and early infant death associated with the sickle-cell disease.

The sickle-cell disease affects millions of people throughout the world and its implications must not be overlooked. The medical world has made great strides in research and treatment of this disease. Further genetic analysis in the development of innovative therapeutic agents provides a promising future for sickle-cell patients. With proper treatment and a healthy lifestyle, the life expectancy will continue to increase for patients who are suffering from the sickle-cell disease.

SIMPSON, GEORGE GAYLORD (1902–1984)

Born in Chicago, George Gaylord Simpson, probably the most influential paleontological thinker of the mid-20th century, was trained at Yale in vertebrate paleontology. In 1927 he took up a curatorial position in fossil mammals at the American Museum

of Natural History, where he spent most of his career before proceeding to Harvard and then to the University of Arizona. Together with his American Museum colleague, the ornithologist Ernst Mayr, and the Columbia University geneticist Theodosius Dobzhansky, Simpson was one of the three main architects of what became known as the “Evolutionary Synthesis.”

Following the rediscovery of the principles of Mendelian genetics in 1900, evolutionary science entered a period of ferment in which all possible avenues for explaining the emergence and establishment of evolutionary novelties were explored. Most of these explorations departed quite radically from purely Darwinian notions of natural selection—which were, indeed, somewhat out of fashion in the opening decades of the 20th century. During the 1920s, however, a series of contributions by such notables as R. A. Fisher, J. B. S. Haldane, and Sewall Wright placed the emerging science of population genetics on a solid mathematical footing, focusing attention upon processes influencing the survival and propagation of particular alleles in populations. These new perspectives attracted the attention of evolutionary biologists from other fields, and rapidly formed the foundation for a new view of the evolutionary process based on Darwinian principles. Simpson’s book *Tempo and Mode in Evolution* (1944), written in trying conditions while he was in the U.S. Army during WWII, is credited, along with Dobzhansky’s *Genetics and the Origin of Species* (1937) and Mayr’s *Systematics and the Origin of Species* (1942), with setting the foundations for the neo-Darwinian view of the evolutionary process that was to dominate in biology for the next half-century.

Particularly in its post-1950 “hardened” form, the Synthesis taught that most, even all, evolutionary phenomena could be traced back to gradual, generation-by-generation changes in population gene frequencies under the guidance of natural selection. Simpson’s particular contribution to the Synthesis lay in the eloquence and erudition of his attempt to reconcile the “gaps” in the fossil record with a linear notion of evolutionary process. In Simpson’s view, the larger gaps—which he regarded as real, rather than as artifacts of the record’s completeness—equated with episodes of fast evolution (“tachytely”) which, like the slower episodes (“bradytely”) that produced smaller gaps, resulted from the same basic set of “determinants”—population sizes and variabilities, generation

lengths, mutation rates, selection pressures, and so on. It was differences in the combination of determinants that gave rise to differing evolutionary patterns. As an extension of this line of reasoning, Simpson saw species not as discrete entities but as arbitrarily delineated segments of evolving lineages.

In addition to his very considerable and influential theoretical output, Simpson was a phenomenally productive systematic paleontologist whose interests ranged widely. He is probably best remembered for his studies of horse phylogeny, but he was also a major influence in paleoanthropology, especially around the time that this field capitulated to the Synthesis in the 1950s and 1960s.

SIMULACRA

Simulacra (sing. *simulacrum*) refers in contemporary social science discourse to multiple copies that have no original or, in Baudrillard's words, "models of a real without origin or reality." The concept has emerged in postmodern social theory as a key term for talking about commodification, intellectual property, popular culture, and multinational cultural flows. It is usually closely linked to the concept of the *hyperreal*, simulated realities that are experienced as more real than the realities for which they substitute.

The term originates with Plato, who used it to distinguish between two modes of representation. Whereas the *icon* is a representation that participates in the idea of the thing it represents, the simulacrum captures only the outer form of things. The idea of the simulacrum was borrowed by social theorists Jean Baudrillard, Fredric Jameson, and Giles Deleuze and

developed to analyze and critique aspects of modern and postmodern society.

Fredric Jameson makes simulacra a touchstone for his conceptualization of postmodernism. His primary example is photorealism, in which people create paintings that are copies not of real things but of photographs of real things. Deleuze furthers (and diverges from) this argument by pointing out that beyond a certain point, the simulacrum is not a copy twice removed but rather a phenomenon of a different nature altogether, something that undermines the normal distinction drawn between copy and model. A copy, no matter how many times removed, is nonetheless defined by some relationship to an original. A copy, in other words, is always made in order to stand in for its model. A simulacrum, on the other hand, takes on a life of its own. Simulacrum, in this sense, is a perfect descriptor for the synergistic blend of commodified texts and goods that make up an increasingly large component of contemporary popular culture.

The most complete theorization of simulacrum comes from Jean Baudrillard's essays *Simulation* and *America*. Baudrillard argues that the distinction between mere copies of copies and simulacra can be understood as a series of stages:

Representation. The image is the reflection of a basic reality.

Counterfeit. The image masks a basic reality.

Simulation. The image masks the absence of a basic reality.

Simulacrum. The image bears no relation to any reality.

To illustrate these, it is useful to take examples from popular culture. Consider, for example, the life of Zorro as a popular culture form spanning 80 years of time and three continents of production. The "basic reality" is the novel by Johnston McCulley, first published in 1919. Over its span, Zorro has gone through all the stages described by Baudrillard:

1. *Representation*. At this stage, we find signification through reference. This is the realm of the sequel or the movie version of the novel. Here we find the 1920 Douglas Fairbanks film *The Mark of Zorro* "based on the novel by Johnston McCulley" and McCulley's own four sequel novels and 50 short stories.

2. *Counterfeit*. Here we find the dozens of reinventions of the film that sprang up in the wake of *The Mark*

of *Zorro's* success. Borrowing signs from that film, they re-create Zorro but weave the character into new narratives that are not consistent with the original film or the novel. The new adventures of Zorro in these films *imply* an original story, but do not make it explicit or seek consistency with earlier Zorro texts. Zorro may have won a bride in a previous film; here he is courting another. He may have been unmasked at the end of the original film, yet here no one knows who he is.

3. *Simulation*. There is no Zorro in *Zorro's Black Whip* (1940) or in *Don Daredevil Rides Again* (1951), or in several other films and stories featuring the image of the black masked swordsman. The Black Whip resembles the Zorro of earlier films (except for her gender), but aside from his name in the title, there is no mention of Zorro in any episode of the serial. Zorro is absent as a referent, yet his costume, his weapons, and his name indexically link these films to the character. "Zorro" has become an absent signifier into which new meanings can be poured.

4. *Simulacrum*. A blonde, teenaged Zorro swash-buckles his way through the 1975 animated TV series *The Legend of Zorro*. Two rival queens hire Samson and Zorro, respectively, to recover a dead king's will in *Zorro Contra Maciste* (1963). Zorro encounters Dracula in one comic book incarnation and crosses swords with the Three Musketeers in another. Four different Zorro action figures graft Zorro's head to metallic bodies with bulging biceps and six-pack abs that more resemble other cyborg action figures than the "gay renegade" of old California. In these incarnations, the signifiers of Zorro remain intact yet disembedded from any of the narratives that originally constructed its meanings.

Baudrillard claims that America, in particular, is the perfect "simulation society," an artificial world constructed of signs without reality. Modern Americans are, he writes, more likely to compare the real to representations of it than the other way around: to compare a sunset to a painting or to compare experience of a place to the images they have seen of it. He argues further that Disneyland and Disney World, with their "Main Street, USA" and other simulations of America that exist only in the imagination, are the most perfect examples of the American simulation society.

But simulacra are by no means limited to the United States. More and more popular culture fits the notion of simulacra. In particular, much of contemporary

children's popular culture is released in simultaneous synergistic packages of electronic games, television series, movies, collectors' cards, and other commodities. None of these are spin-offs of the others—or they all are. Either way, they clearly fit the definition of simulacra.

Siwalik Hills is a range of foothills of the Himalayas extending from northeast Pakistan through northern India to southwest Nepal, famous for its rich fossil beds containing extinct apes and other primates. The region has a long history of paleontological research and exploration, beginning in the early part of the 19th century. However, the most intensive research has been conducted since 1973 in the Potwar Plateau of Pakistan by David Pilbeam and his colleagues.

The fossiliferous sediments in the Siwalik Hills are very extensive, measuring several kilometers in thickness. During the Miocene (23–5 million years ago), active uplift of the Himalayas led to increased erosion, and this produced massive volumes of sediment that were deposited by floodplains and rivers. The sediments range in age from more than 22 million years old to less than 1 million years old and provide a remarkably complete fossil record by which to document the evolutionary history of mammals in the region. The sedimentary sequence in the Potwar Plateau has been subdivided into a series of geological formations: Kamlial Formation (18–14 million years old), Chinji Formation (14–10 million years old), Nagri Formation (10–8 million years old), Dhok

Pathan Formation (8–5 million years old), and Soan Formation (5–1 million years old).

In addition to fossil apes (hominoids), several species of strepsirhines (sivaladapids and lorisids) and cercopithecoids (Old World monkeys) are known from the Siwalik Hills. In addition, a few isolated teeth from the middle Miocene Kamliar Formation (16 million years ago) belong to a small catarrhine primate (about 3–4 kg) that is quite similar dentally to contemporary species from China and East Africa. They appear to belong to a lineage of primitive catarrhines that originated prior to the divergence of the Old World monkeys and apes. Two groups of fossil strepsirhine primates are known from the Siwalik Hills. The sivaladapids, represented by *Indraloris* and *Sivaladapis* from the Chinji and Nagri Formations (14–9 million years ago), are the last surviving members of a diverse group of strepsirhines (the Adapiformes) that inhabited Europe during the Eocene (34–55 million years ago). They are medium-sized (4–7 kg), arboreal primates with specialized teeth for leaf eating. Slightly later in time, from the Dhok Pathan Formation (8 million years ago), is *Nycticeboides*, which appears to be closely related to the living slow loris from Southeast Asia. Old World monkeys or cercopithecoids first appear in the Siwalik Hills in the Dhok Pathan Formation and are the only fossil primates known from the Soan Formation. *Presbytis sivalensis* (or *Semnopithecus sivalensis*) from the Dhok Pathan Formation (7–8 million years ago) is a small colobine monkey related to the living Asian langurs. A baboon-like cercopithecine (*Procynocephalus subhimalayanus*) and a macaque (*Macaca palaeindica*) are recorded in the Soan Formation at 2.0–3.5 million years ago, while a gelada baboon, *Theropithecus oswaldi delsoni*, is known from somewhat younger deposits dating to 1.5–0.9 million years ago.

The most common and best-known fossil ape in the Siwalik Hills is *Sivapithecus*. Three species are represented: *S. indicus* (12.5–10.5 million years ago), *S. parvada* (10 million years ago), and *S. sivalensis* (8.5–9.5 million years ago). Smaller, female specimens of *Sivapithecus* were previously included in the genus *Ramapithecus*, once considered to be a human ancestor. However, with the recovery of additional specimens, especially a partial skull of *S. sivalensis*, it became clear that *Sivapithecus* was more closely related to the orangutan. Other fossil apes from the Siwalik Hills include “*Sivapithecus*” *simonsi* (10.5–11.5 million years

ago), which is probably more closely related to *Dryopithecus* from the later Miocene of Europe than to *Sivapithecus*, and *Gigantopithecus giganteus*, the largest of the Siwalik apes (about the size of a modern gorilla), which is known from the Dhok Pathan Formation (6.5–7.0 million years ago).

Contemporary images and theories of slavery have become deeply entwined with the constructions of modern slavery in the New World. This entwinement is due to the reality that the institution of slavery was the primary mold of the conquered New World. From its overall scale, its rationalization of labor, and its integration within a capitalist mode of production to its legally sanctioned discipline of the body and its powerful demographic and geographic effects, slavery in the New World constituted the most ambitious enterprise of this sort. From the 16th to the 19th century, nearly 11 million people were shipped as slaves to the Americas and were forced in what was historically unprecedented to labor for the remainder of their lives in societies run by culturally, linguistically, and ethnically distinct people. Not surprisingly, anthropology's images and theories have drawn largely from the abundant historiography of slavery in the United States and the Caribbean. They thus tend to depict slavery in its American and Caribbean plantation form, where African slaves were property (as legally defined in the Code Noir), subject to compulsory labor, familial separations, and systematic dehumanization. Variations in these representations do exist, however, including the idyllic way Brazilian slavery has been represented by Gilberto Freyre (contrasted with the institution of slavery in the United

States). Despite its scale and historical importance, modern Euro-American slavery was but one incarnation of slavery among many others present across a wide spectrum of societies. Historians, in particular, have generated a substantial body of work on the patterns and pervasiveness of slavery in Europe going back to the Greeks and Romans and persisting through medieval Christendom.

Early anthropological investigations focused on slavery as a social, quasieconomic institution, and monographs from the period document the extent to which different societies practiced slavery. These first writings forwarded two main concepts, warfare and cannibalism, as the explanatory sources of slavery. The potential production value of enslaving enemy bodies captured during wartime came to be valued over immediate killing. Cannibalism, with its rituals of keeping captives before killing them, also reaped the benefits of forcing their captives into labor during these waiting periods. Anthropology proffered that as humankind moved toward more complex agricultural and sedentary societies, the economic rationale for slavery grew, spawning the exploitation of new sources for obtaining slave labor. Accordingly, profiteers obtained slaves through kidnapping, legal punishment, conquest, debt, piracy, and trafficking.

To this point, anthropology articulated its discussions and commentary on slavery through an evolutionary framework. From this evolutionist view, modern slavery in the New World was a remnant of past primitive practices—as anachronism—rather than constitutive of the creative forces of modern times, specifically the intersection of agrarian capitalism with a colonialist racial ideology. Contemporary anthropological debates on slavery have sought to avoid interpretations that reduce slavery to its New World institutionalization. This endeavor, combined with the availability of extensive materials on the diversities of practices of slavery in different societies, most notably Africa (with the works of Igor Kopytoff, Suzanne Miers, and Claude Meillassoux) and South Asia, have led to the reevaluation of key characteristics that historians and social scientists used to define slavery, namely property and compulsory labor, both derived from the conceptualization of slavery in the New World. Some anthropologists in fact question the use of the legal notion “property” as a universal construct, which, Kopytoff describes as changing “with different cultural and socioeconomic contexts.”

The rights that the notion implies do not provide an understanding of other forms of slavery, especially where kinship and community relations figure centrally, and due to the structure of the political economy, the commodification of the bodies of others is not at issue. In the same vein, compulsive labor, so much a distinctive feature of the New World experience, brackets an understanding of those forms of slavery (for example, domestic slaves or slave educators in ancient Rome) that do not necessarily imply the same level of socially alienated compulsory work. Kopytoff suggests that conceptualizing slavery in terms of property and compulsory labor can only lead to the opposition slavery versus “freedom,” which is a Western Enlightenment construct, obscuring a more complex relationship with other categories (such as citizenship and other cultural modes of identification). Meillassoux and Kopytoff’s works have contributed to this displacement of concerns regarding slave and slavery by conceptualizing slavery as a dominant institution in Africa, in rupture with traditional Western constructs.

Anthropology has not been fully at ease in theorizing slavery. Indeed, a thorough review of anthropological research on slavery does not take us much further than it took Kopytoff or Meillassoux, almost a quarter of a century ago. It is perhaps the recency and even the contemporaneity of the phenomenon that define this uneasiness and “silence” of anthropology to generate serious and sustained theoretical considerations. Moreover, the study of slavery from the anthropological perspective presupposes an epistemological evaluation of the condition for a possible legitimacy of its own discourse about an object that partially was instituted out of a shared rationalization process. Anthropological narratives about slavery emerged at the core of a crucial contradiction in which both, modern consciousness about slavery and the “primitive other,” *raison d’être* of classical anthropology, were engendered by the same Enlightenment project. The latter provided the analytical tools to think about primitive societies and their primitive practices—such as slavery—while, paradoxically, its enlightened philosophers were claiming freedom for those outside the dark world of slavery to guide the path of humanity. The task for anthropology is thus to evacuate the heavy ethnocentric biases that are embedded in these analytical categories to think about societies and slavery and to move beyond the established analytical framework

that is too present in the traditional historiography and sociology of slavery.

SMITH, GRAFTON ELLIOT (1871–1937)

The story of Grafton Elliot Smith is the story of the brilliant colonial boy who did well for himself. He was born on August 15, 1871 in Grafton, New South Wales, the son of Stephen Sheldrick Smith, a teacher, and his wife, Mary Jane Evens. Smith soon showed his precocious intelligence, developing an interest in anatomy after dissecting a shark. He was able to attend the University of Sydney, graduating with an MD in 1895 and winning a gold medal for his thesis on the anatomy of the brain in non-placental mammals. The following year, Smith was awarded a traveling scholarship to study for his PhD at Cambridge University, and in 1899 he completed his extraordinary ascent by being elected a Fellow of St. John's College, Cambridge.

While Smith's rise was rapid, his colonial origins meant he was at a disadvantage for the best appointments in Britain, so in 1900 he went to Egypt as the first occupant of the Chair of Anatomy at the Cairo School of Medicine, a post he held until 1909. With his colleague Fredrick Wood Jones (1879–1954), Smith investigated thousands of mummified remains, diagnosing many diseases along the way (gout, leprosy, smallpox, and tuberculosis among them). This work vastly extended contemporary knowledge

of life in ancient Egypt. For his work on an ancient brain recovered by archaeologists, and as anatomical advisor to the archaeological survey of Nubia (now northern Sudan), Smith was elected a Fellow of the Royal Society in 1907. This work complemented a major project of cataloguing brains that Smith undertook before going to Egypt and which was published in 1902. Smith's Egyptian work was published as *The Royal Mummies* (1912) and remains his principal contribution to science.

The second, and less helpful, phase of Smith's career began when he returned to the United Kingdom in 1909 to take up the Chair of Anatomy at Manchester University, a position he held until 1919. It was at Manchester that Smith developed his controversial theory, which became known as diffusionism. It was Smith's belief that *Homo sapiens* emanated from central Asia rather than from Africa. This view was not unique to Smith; its best known advocate was Ernst Haeckel (1834–1919). Smith outlined his theory of diffusionism in a series of works, principally *The Diffusion of Culture* (1933). Smith's extreme version of diffusionism failed to convince during his lifetime and has not been revisited. After his death, a longstanding colleague, A. C. Haddon (1855–1940), noted tactfully that Smith's zeal for diffusionism outran his discretion.

Less controversial then than it is now, Smith also subscribed to some racist readings of evolution. He had no doubt that Australian Aborigines were “the most primitive race . . . which represents the survival with comparatively slight modification of perhaps the primitive type of the species.” Smith then saw the racial order move progressively upwards through the Africans, the Mongols, and on toward the “Alpine Race,” which in turn was divided between its Mediterranean and Nordic Races, “in which the latter of which the reduction of pigment was carried a stage further to produce the blondest of all human beings.” Smith's racism was not obsessive or malevolent, as it was with some of his contemporaries. For him it was simply the clear testimony of science.

Smith was a talented popularizer who wrote several works designed for the non-specialist reader. For example, *The Search for Man's Ancestors* (1931) was part of an influential popular science series called The Forum Series, published by Watts & Co. for the Rationalist Press Association (RPA). Even more influential was another RPA series called the Thinker's Library, in which Smith had a book titled *In the Beginning: The Origin of Civilization* (1932). Smith

became an Honorary Associate of the RPA in 1925 and he was knighted in 1934.

It is perhaps inevitable that Smith has been accused of being the mastermind behind the Piltdown fraud. This theory, always unlikely, was squashed with findings in 2003 that definitively placed responsibility back on the original suspect, Charles Dawson, the man who found the Piltdown pieces.

Smith's health was eroded in the 1930s by a series of strokes brought on by hypertension and diabetes. He died on January 1, 1937 after another stroke. He was survived by his wife of 37 years, Kathleen, and his three sons. Each year the Australian Neuroscience Society presents the Sir Grafton Elliot Smith Award to the best emerging neuroscientist.

SMITH, WILLIAM (1769–1839)

William Smith was born on March 23, 1769 in Churchill, Oxfordshire, England, the first son of five children of the village blacksmith. He had a meager formal education but had a natural curiosity concerning local rocks, fossils, and geography. When he was eight years old, his father died, leaving the family in dire circumstances and resulting in his education shifting to the more practical aspects of surveying, geometry, landscape study, and mapping.

At eighteen he became an assistant surveyor with the office of the prominent surveyor Edward Webb, which provided Smith the opportunity to travel extensively and study the landscape in depth as part of his employment. Through these small jobs, he gained a reputation and, in 1791, started a business of his own. By 1794, he was supervising the digging of the Somerset Canal, a six-year undertaking that necessitated a meticulous study of the rock structures to determine the best possible route. It was during this time, together with the mapping of potential coal mining sites, that Smith made the important discovery that

certain beds had characteristic fossils and that they were unique to that stratum and that period of geologic history. As his travels and rock collections continued, his theory that a particular stratum could be positively identified solely by the fossil remains found in it was reinforced again and again. These observations would be a basis for the conclusion of later evolutionists of the law of faunal succession: in general, in the development of life on the planet, fossils in the layers of sedimentary rocks in any location are in a definite sequence from the bottom to the surface of a section, with the youngest stratum on the top. This concept was virtually unknown to scientists of the period.

To put his theory to work, Smith coordinated his notes and first began to draw local maps—not of the surface topography of outcrops, nor of the composition of the rocks, but of their strategic order, using the fossil record as the classifier. Twenty-one counties were produced. These were new kinds of maps, with the unseen world below the surface on display, used as a device to predict with accuracy what rocks would appear and what fossils would be present.

After confirming the validity of the local maps and with his employment with various canal-building companies ended, Smith had a series of engineering jobs that enabled him to again travel to various parts of England with side trips to Wales. His vision was to make a geologic map of all of England and Wales using his principles of fossil position. This he completed in 1815 and updated in 1820. It represents the first true geologic map anywhere in the world. It is displayed at Burlington House, near London's Piccadilly.

Tragically, this map was at first overlooked by members of the scientific community. They reacted to Smith's humble beginnings and limited education when compared to their “learned mentality.”

Later in his life, in 1831, Smith was awarded the Geologic Society of London's highest honor, the first Wollaston Medal for outstanding achievement in geology—work that contributed greatly to the historical development of the new science of geology and earned him a title of the Father of English Geology.

 SMUTS, BARBARA B.

It is not easy to understand human behavior in terms of social relationships. Many books have been written on the subject and many more will be written in the future. Perhaps this is due to the fact that an interest in social interactions, especially between males and females, will always be a subject of inquiry for us. However, a University of Michigan professor has made a valid attempt at giving us certain insights about human relationships between the sexes based on her many years of field research where she studied the social relationships of primates.

Dr. Smuts received her PhD from Stanford University; as a scholar she has focused on primates and analyzed the relationship between males and females while conducting field research studies. What she observed and learned in her studies may help us to better understand similar relations between humans of different genders. By having a better understanding of nonhuman social interactive relationships, we could be in a better position to understand our own forms of human behavior and perhaps even to improve on them. Such information is becoming more important because we are at a time in our society when more attention is being given to male and female interpersonal relationships. Dr. Smuts's works will increase in value because of their contributions to a better understanding of these roles.

 SOCIAL CHANGE

Human relations may be considered as patterned interactions over time. Thus, temporal change and continuity are constant and fundamental features of the human condition. In this perspective, the typical usage of the social change concept—as only applying when a “normal” state of affairs is radically and

rapidly altered—involves several flawed assumptions, including the idea that stasis is normal and that only change needs explanation. The alternative is to think of our key topics, including society, culture, and nature, as processual—as unfolding over time. Anthropology has a twofold relationship to social change. On the one hand, the long time period of human biological and cultural evolution provides bountiful evidence of social change; on the other hand, the microscopic time and space perspective of ethnography favors static views of culture and society and thus misleadingly renders change abnormal and exogenous.

Cultural evolution is generally used for major changes in social organization that have taken place over the length of human prehistory and history, involving the emergence of ranking and stratification, states and bureaucracies, specialized occupations, cities, and so on. Empirical generalizations about and theories of cultural evolution abounded in the 18th and 19th century. Among the most important are found in the works of Karl Marx and Friedrich Engels, Herbert Spencer, Edward Burnett Tylor, and Lewis Henry Morgan. Typically, these authors approached social change as a series of stages with distinctive lists of characteristics, such as Morgan's memorable, if patronizing, “savagery, barbarism, and civilization,” further subdivided into lower, middle, and upper units (resulting in odd terms such as “upper savagery,” whose marker was the invention of the bow and arrow). Such stage theories tended to assume progress over time, arrogantly envisioning the most powerful European-based societies of the world as the pinnacle of change (Marx and Engels, however, envisioned a further step forward, to “communism”). Clearly, then, cultural evolution models reflected not just “pure” scholarship but also the worldview of European imperialism and emergent capitalism.

At the end of the 19th and beginning of the 20th centuries, Franz Boas emphatically criticized the flaws of stage theories, such as their rigidity and egregious speculation. Nevertheless, he also addressed change as a kaleidoscopic flow of influences among cultures—so-called historical particularism. His interest in social change waned, however, when confronted by recent changes in non-Western cultures impacted by the West, which he tended to ignore. The late Boasians (such as Alexander Lesser) initiated the study of recent history among Native Americans, but this was overshadowed by the revival of stage theories

of cultural evolution under the auspices of Leslie White and Julian Steward. While White reasserted the single line of advance posited by 19th-century theorists, Steward more subtly argued for many regional histories, which were partly unique but across which one sometimes finds comparable and thus generalizable transitions, such as the formation of class- and state-based societies. Without doubt, the revival of evolutionary models was shaped by the post-World War II triumph of United States technological, political, and economic power.

Emerging from White and Steward, there have been two important lines of inquiry. One explores the causes of change between stages—is it technological improvement, especially control over energy? Is it gradually growing populations? Is it sacred consensus? Is it political coercion, and if so, based on what? Territorial circumscription? Management of irrigation? The other questions the stage approach—at least in its most schematic format—emphasizing complex systems dynamics and ambiguous, transitional cases, while at the same time retaining the insight that there are broad tendencies over time toward inequality and centralization of power.

Alongside these developments in the course of the 20th century arose the functionalist view of societies (which can be crudely summarized as “everything works together, all in the present”), which was shaped by the development of sustained fieldwork-based ethnography as a research method. Ethnography has many virtues, but we noted its static bias above, a characteristic example being Bronislaw Malinowski’s omission of migratory wage labor to plantations by young men in his Trobriands ethnography. Since then, British social anthropology struggled with how to insert social change. Godfrey Wilson pioneered by looking at the effects of mine labor and then unemployment during the Great Depression in southern Africa; following him, the researchers of the Rhodes-Livingston Institute and the “Manchester school” of social anthropology made change, conflict, and adjustment their principal agenda. Within structural-functional anthropology, Edmund Leach outlined a dynamic, if cyclical, model in *Political Systems of Highland Burma*. And most radically (in political as well as intellectual terms), Peter Worsley challenged the functionalist bias toward cycling back to stasis by examining revolutionary millenarian movements among non-Western peoples.

This set the stage for anthropology’s increasing attention to recent history as the context for inherently processual culture. The background was the tumultuous world of the 1960s, filled with rebellions against colonial masters, communist bureaucrats, and inherited intellectual verities. The key scholar was Eric Wolf, whose magisterial synthesis *Europe and the People Without History* proposed that the diverse modern cases studied by anthropologists form part of one worldwide network, constantly undergoing change through the unfolding of global capitalism. In this history, European imperialists and non-European peoples are mutually causal and equally dynamic. June Nash, Eleanor Leacock, Sidney Mintz, Talal Asad, Worsley, and many other anthropologists contributed to this perspective, as well as Immanuel Wallerstein, Samir Amin, Andre Gunder Frank, and others who developed “world system theory.”

No longer could scholars view non-Western peoples as occupying timeless “tradition” until “modernity” was imposed from outside, whether as “progress” or “destruction.” Instead, certain characteristic cultural qualities of “modernity”—intensive non-face-to-face communication, say, or citizenship in imagined collectivities—emerge from a dynamic interaction of cultural segments throughout the world system, with local inflections as well as global commonalities. Debatably, some scholars posit that these changes are now so intense that we live in a foundationless “postmodern” period, one of total “globalization.” Even if the language of these approaches is overheated, social change is now central rather than intrusive in the study of anthropology.

SOCIAL STRUCTURES

Social structure has been used in anthropology as the descriptor for a variety of conceptualizations of human organization. The term, wrote Claude Lévi-Strauss, “has nothing to do with empirical reality but with models which are built up after it.” The building up of such models was a central preoccupation in anthropology in the mid-20th century. These theorists built on an ancient conversation dating from Plato, Ibn Khaldûn, and Vico and stretching to the figures who laid the foundations for 20th-century social theorizing: Freud, Marx, Durkheim, and Weber. The models addressed social phenomena ranging from marriage rules to political forms. Several features of this conversation in anthropology distinguished it from a similar one in sociology taking place during the same period in which such themes as class, norms, and inequality were emphasized. These included a concern with non-Western political organization and kinship structures and terminologies, which were shown to be overlapping and in many ways mutually constitutive, and a comparative approach in which a premium was placed on providing as much data from as diverse sources as possible.

Structural-Functionalism

Several theorists, in what came to be known as “structural-functionalist” anthropology, also known as “British social anthropology,” addressed the question of social structure as a part of their larger interest in the interconnectedness of individuals and societies. They include E. E. Evans-Pritchard, Meyer Fortes, and A. R. Radcliffe-Brown. Each regarded kinship as one of the chief entrées into social structure. Their approach was strongly comparative. They sought to identify the “rules” of descent that governed the composition of kin groups such as patrilineages, clans, and tribes, units they portrayed as integral to political organization. The structural-functionalists were later criticized by Harris for drawing universalistic conclusions from historically situated data, for example by not assigning enough weight to colonialism, the slave trade, and other encroachments on local political organization.

Radcliffe-Brown argued that social structures were “just as real as are living organisms” and that social structure was “the set of actually existing relations, at

a given moment of time, which link together human beings”. He differentiated between his own approach, in which social structure encompassed “all social relations of person to person” and “the differentiation of individuals and of classes by their social role,” and that of Evans-Pritchard, whom he saw as using the term “to refer only to persistent social groups” in his 1940 ethnography of the Nuer.

Evans-Pritchard’s ethnography was the best known example of “descent theory,” in which the structural-functionalists argued that segmentary lineages formed the basis for the societies, most of which were in Africa, that they presented as examples. Lineages were shown to unite and divide along blood lines. Their argument thus posited lineal underpinnings for kinship and political organization. What mattered to the individuals who comprised these systems, they argued, was related to the composition of the groups over time rather than laterally, in the present.

Comparative Anthropology

While the structural-functionalists were developing their theories of social structure in Britain, George Peter Murdock led the way in promoting a comparative approach in the United States. In 1949 he published *Social Structure*, in which he posited a model of human organization whereby human social structures were seen to conform to natural laws just as those recognized in the hard sciences. Murdock made his assertions based on (what came to be called) the Human Relations Area Files, a database he created in which features of numerous cultures were codified and described. This allowed him, and many others since, to compare structural features and to greatly advance the comparative method in anthropology. Murdock argued, for example, that postmarital residence carried more weight than lineage structure in influencing kinship terminologies.

Lévi-Straussian Structuralism

Claude Lévi-Strauss was known for theorizing as to the ultimate rootedness of culture and social organization in the structure of the human mind. He saw the study of social structure as entailing the systematic investigation of an “order of elements” that includes kinship and descent systems and marriage rules, and an “order of orders” in which “anthropology considers the whole social fabric as a network of

different types of orders.” In this latter category, he included “lived in” orders such as the economic and political, and the “thought of” orders that are “external to objective reality” such as myth and religion. He argued against Radcliffe-Brown’s model, preferring not to see these orders as concrete but as cognition-based.

In *Elementary Structures of Kinship* (1969), Lévi-Strauss pointed to the universality of the incest taboo and theorized that the prohibition of incest had led to the initiation of marriage rules, which dictated who could marry whom. Lineage groups encouraged or discouraged marriages between or within kin groups for reasons that had to do with the avoidance of incest (however defined by the particular group) and the building of alliances between groups through marriage. “Alliance theory,” as this came to be called, thus challenged descent theory by arguing for inter-group dynamics as more socially constitutive than a concern with blood lines.

Interpretivism and Practice Theory

Theorizing about “social structure” had waned in anthropology by the end of the 1960s and given way to what came to be called “interpretivism,” a movement mainly associated with Clifford Geertz but furthered by many others. The interpretivists endeavored to improve on social structural models that had begun to seem static and ungrounded. Victor Turner, for example, sought to portray “social structure in action” in his work on Ndembu rituals and other social practices. Sherry Ortner, in an important survey of trends in anthropological theory, declared that a new emphasis on “practice” had emerged in anthropology. She mentions structural Marxism, with its emphasis on “beliefs, values [and] classifications,” as an early threat to social structure, but ultimately relegates it to those anthropologies that assumed “that human action and historical processes are almost entirely structurally or systematically determined.” With practice theory, however, came a new emphasis on the “agent, actor, person, self, individual [or] subject.” An actor, by definition, possessed agency, the ability to act. Practice theorists, also called “poststructuralists,” sought a balance between structure and agency. The leading theorist in this vein was Pierre Bourdieu, whose idea of “habitus” offers a dialectical solution to the problem of reconciling structure and agency, an approach he calls “genetic structuralism.” A habitus is a “system of acquired

dispositions functioning on the practical level as categories of perception and assessment or as classificatory principles as well as being the organizing principles of action.” Anthony Giddens’s theory of “structuration” accomplishes a similar purpose by offering a model that encompasses both structure and action and elaborates on their mutual constitution.

Social structure no longer enjoys a central place in mainstream anthropology. However the current emphasis on agents, which sought to correct for an overemphasis on structure, is beginning to lead to a reappraisal of structure, albeit in new forms and from new angles, in theorizing as to the nature of individuals and groups and how they shape each other. Interdisciplinary subfields such as network analysis trace their origins to Radcliffe-Brown and his contemporaries. Social structure stands as a key idea in 20th-century anthropology. Moreover, its influence continues as one of the main ideas that made post-structuralism possible, and as a precursor to subfields of social analysis utilizing new empirical methods never anticipated by its originators.

SOCIALIZATION

Socialization as a concept originated in sociology and refers most simply to the process of learning to pattern behavior and adapt to society’s norms, rules, and strictures for playing specific social roles. Although it has not been central to British social anthropology, the discipline’s focus on society has contributed to a heavier emphasis on socialization than in American cultural anthropology, where the closely related concept of enculturation has been more important. Enculturation refers to the way individuals learn to pattern their thinking and feeling in culturally

appropriate ways. Nonetheless, since all human beings undergo both kinds of learning, many anthropologists use the terms almost interchangeably to refer to the entire learning process necessary to be able to function in any given society or culture.

Studies of both socialization and enculturation in anthropology have tended to be grounded in theories of cognitive development that are holistic and social, rather than those that are more universalizing. George Herbert Mead and Lev Vygotsky are two popular sources for anthropologists to turn to because both thinkers focused on the social aspects of cognitive development. Both wrote about the importance of mastering symbols as a marker of maturity and, especially Mead, about the centrality of role playing in the learning process.

The earliest studies of socialization in anthropology focused largely on the ways that children and other immature members of society imitate the behaviors of adults or other mature members. Indeed, a review of the majority of the ethnographies of childhood, from the first by F. C. Spencer in 1899 up to the present, reveals that imitation is central to the socialization process in virtually every culture on earth. Classic examples of both American cultural anthropology, such as Margaret Mead's study of growing up on the island of Manus near New Guinea, and British social anthropology, such as Meyer Fortes's work with the Tallensi in East Africa, focus on the ways children rehearse interests, skills, feelings, behaviors, and other aspects of life in their culture and society without long-term repercussions for any mistakes.

In addition, these and many other ethnographers indicate that childrearing is actually secondary to the "culture-seeking" activities of children themselves. This is not to deny the role of teaching, other kinds of instruction, and, especially, such corrective feedback as threats, teasing, and shaming in the socialization and enculturation processes, but rather to emphasize both the agency of children and, more important, the near impossibility of transmitting most cultural knowledge in verbal form. In this way, the centrality of participant observation among both anthropologists in the field and young children everywhere have the same basis. Indeed, many societies actually deny that children, especially those under the age of six or seven, have any ability to understand the world around them, make appropriate decisions about their thoughts and feelings, or exercise control over their

behavior. As a result, few people in these societies bother to teach young children at all, through either verbal or other kinds of training. They are left to learn through observation and imitative play, sometimes with the threat of censure if they act inappropriately, but often (especially outside of the West) without a formal lesson on how to act.

Despite the early emphasis on imitation in ethnographies of childhood, as well as the simplified definition of socialization given to many introductory students in anthropology—"the process of learning to live in society"—anthropologists have generally not thought of the process as simple replication. Imitation is always selective and even creative. For example, Margaret Mead noted with interest that children on Manus showed almost no interest in those activities deemed most important by adults, notably religion and ritual exchanges. They were very choosy in deciding which of their elders' behaviors to imitate in play. At the same time, children's imitation often both stems from and fosters a sense of identification with those of higher status, whether adults or older children. Eventually, this imitation develops into actual assistance in the carrying out of tasks and then into independent action. Some cultures also assign young children to this apprentice-like role, in which they are expected to perform family chores under the guidance of an older mentor, in the process learning through both imitation and guided instruction.

Another reason that imitation could never be seen as simple replication is because the societies in which most anthropologists have engaged in their studies of the socialization process are themselves undergoing tremendous change. This change, whether due to colonialism, postcolonial state formation, or globalization, has resulted in "socialization crises," in which adults' knowledge of the world is relatively useless to children educated by such outsiders as missionaries, state education systems, or the media. Studies of socialization, as well as adult resocialization, in these kinds of societies have tended to focus on the ways that old and new symbol systems have been negotiated, combined, and confronted by all actors for the benefit of themselves or their societies.

A theoretical problem with the notion of imitation has also emerged in the social sciences more generally following neo-Marxist and later postmodern critiques of the way that using the universalizing label "socialization" actually hides, or mystifies, the

reproduction of specific class, race, gender, and other hegemonic systems. From this perspective, socialization must be studied as dialogic processes, in which individuals confront multiple socializations into family, community, school, church, and a host of other institutions over the course of their entire life, post-childhood socializations often being referred to as secondary socializations. The influences of these and many other institutions and symbol systems act simultaneously and often in contradictory ways to locate individuals within the matrix of society. This view aims to replace the traditional notion of socialization with one that recognizes that all individuals have multiple subject positions available to them, as well as multiple limitations based on race, class, ethnicity, nationality, gender, sexuality, and other factors. It also recognizes that individuals not only absorb ideas, values, skills, and behaviors from elders and others, but they also resist and transform them as well.

SOCIETIES, CLASS

The word *class* comes to us from the Latin *classis*, which referred to the division of Romans according to property. It takes on its modern sense in English from the late 18th century, when the profound socio-political upheavals associated with the French and Industrial Revolutions redrew the social map of Europe. Prior to this time “rank,” “estate,” and “order” were more commonly used to speak of the exploitative self-differentiation of society into functionally inter-related and hierarchically organized sociocultural groupings. Subsequently, most of these meanings were subsumed within “class,” though precisely with the difference that the term no longer automatically connoted a natural or divinely ordained social layering.

Given this volatile history, it is no surprise that there has been little consensus on the definition or even existence of classes. Indeed, it has been argued that class is so hard to define because the meaning of the concept is itself a stake in class struggles. Naturally, many would disagree (perhaps thereby proving the original point).

These conceptual tensions are in play in the anthropology of class and class societies, along with an additional problem. The word, together with its contested meanings, carries the birthmarks of the European sociocultural realm from which it sprang. How then are anthropologists to treat the question of class?

Three basic options may be mentioned. Class can be quietly set aside as insignificant for anthropology on the grounds that the comparatively economically undifferentiated societies traditionally studied by ethnographers are not class societies. Alternatively, class can be employed, but within a restricted compass. Finally, the concept can be wrestled into a new form in the attempt to make it adequate for various kinds of non-Western societies.

The principal social scientific approaches to class have come out of political economy, sociology, and above all, Marxism. For Karl Marx (1818–1883), to speak of classes was to speak of distinct groups of people defined by their ownership and control over productive property or by their lack of it. Class division was the defining aspect of any complex social order and the ruling ideas the ideas of the ruling class.

Neither this, nor any other conception of class, has been central to the main current of anthropological thought. Where appeal has been required to kindred phenomena, categories like stratification, status group, and hierarchy coming out of the Weberian tradition have often been found more serviceable. It is a moot point, however, whether this has been a matter of choosing concepts most appropriate to non-Western societies, as thinkers like Louis Dumont (1911–1998) have argued, or of ignoring class, as Talal Asad has charged.

The point proved especially moot from the mid-1960s on, as increasing political militancy both at home and in the newly postcolonial countries radicalized many anthropologists. Their discipline, some came to think, had historically made class politics disappear behind dubious assumptions about order and consent in traditional non-Western societies.

The evolutionary model of 19th-century anthropology, and the work of Lewis Henry Morgan (1818–1881)

Source: © iStockphoto/Diane Diederich.

in particular, had an ambiguous effect in this regard. To the one side, it furnished arguments accounting for the historical emergence of property-owning classes. To the other, it suggested that the most primordial societies would be classless. The latter was a logical if not an empirical requirement of the model, since class is a social differentiation, and by definition the undifferentiated ultimately predates that which is differentiated. With this supposition in hand, “survivals” of classlessness could be freely discerned in existing “primitive” societies.

Certain major anthropological thinkers in the first half of the 20th century could also be seen to have reinforced a similar result, if from different starting points. Franz Boas (1858–1942) emphasized the study of particular cultures as integrated wholes arising from discrete histories. Bronislaw Malinowski (1884–1942) viewed each society as a composite of parts geared to meeting the biological needs of the individual. A. R. Radcliffe-Brown (1881–1955) conceived of societies as functional units regulated by general laws oriented to ongoing social reproduction. From angles like these, it would be argued, class relations had little chance of getting the attention they deserved.

A shared desire to champion the interests of exploited classes, however, has been no guarantee of

unanimity on the question of the presence or absence of classes in non-Western societies. Ambiguity on this issue was a feature even of the Marxist classics. Friedrich Engels (1820–1895) would famously come to modify the *Communist Manifesto*’s (1848) declaration that the history of all hitherto existing society was the history of class struggles. In footnotes to later editions, the claim was qualified to cover only the period of *written* history. Prior to that time, there was little reason to credit the existence of property-owning classes. Moreover, Marx and Engels were alert to the continuing significance of common ownership in societies that had not yet come fully under the domination of the bourgeoisie.

In their wake, as Yuri Slezkine has detailed, early 20th-century Soviet anthropologists and ethnologists confronted the same dilemma in quite concrete circumstances. They could go hunting for evidence of survivals of primeval common ownership among the “small peoples” of the Soviet Union, or they could seek out disguised forms of class oppression on behalf of indigenous proletariats. In the West, Eleanor Burke Leacock (1922–1987) argued the case for a long era of “primitive communism” prior to the emergence of class societies, while Emmanuel Terray claimed that age and sex could function as classes in precapitalist social formations.

The positions argued by Leacock and Terray, respectively, though both drawing on Marxism, represent two opposed views of the remit of class. Leacock's approach has Marxist tradition on its side. Heavily influenced by Morgan's *Ancient Society* (1877), this tradition underlines the egalitarian nature of early kinship societies and typically conceives of the production of goods as determined by requirements of use. With increases in the productivity of labor, surpluses become available for differential appropriation. This in turn makes possible the emergence of ruling classes utilizing elements of a nascent state to put others to work for them.

One possible problem with this approach, as Maurice Bloch has emphasized, is that Marxism, having made class the linchpin of its theory of society, winds up having little distinctively Marxist to say about apparently classless societies. Instead, it merely reproduces the untenable arguments of 19th-century anthropology about "primitive" society.

An alternative is to dispense entirely with the evolutionary framework and the requirement it imposes to work out which of the canonical "stages" of the organization of the mode of production any given society falls within. This is the option pursued by structuralist Marxists like Bloch, Maurice Godelier, and Terray himself. The difficulty faced by this disparate group was that Marx's categories of thought were generated to explain European capitalist society. Their task, therefore, entailed identifying and extracting those elements of Marxist theory that might promise to be of universal applicability. For some, like Terray, class was one of those elements and could now be extended to understand unequal and exploitative relations in all societies. Others, notably Godelier, have been less than happy with discovering classes among peoples who have, and can have, no intimation of such a thing.

The general question raised by such concerns is a classic one: May we speak of "class society" if and only if people self-consciously define themselves as belonging to a class? Or can class exist as a deep structure, the "hidden secret" of the social order?

In general, it has been easier to argue the reality of class as an objective or "etic" social relation within existing non-Western kinship societies than as an intraculturally recognized or "emic" one. Or at least it has been plausible to make such etic claims within the spatiotemporal catchment area of European world expansion. Tangled in a planetary net of someone

else's making, tribal, band, and rural peoples end up producing primary commodities for international markets; being answerable to local and national military-governmental structures; living off royalties from mining or forestry on their shrinking lands; and consolidating internal elites owing much of their status to monopolistic control over external sources of wealth. But it is another matter altogether that these subjugated peoples should come to see themselves as members of a class. And it is yet a further step that they should define their corporate interests as hostile to that of another class.

Such dilemmas become exacerbated when radical ethnographers attempt to put themselves at the service of nonexistent class struggles. The Africanist Wim van Binsbergen, for example, confronted this situation with the Nkoya of Western Zambia. Van Binsbergen hoped that his analyses of the economic and political condition of the Nkoya might encourage some of them to become militant and class conscious. The Nkoya, however, stubbornly regarded his ethnography as an opportunity to codify their history as a distinct people and bring credit to the splendor of their chieftainship.

Sobering experiences such as van Binsbergen's are no doubt only one among many of the reasons for the current receding tide of confident Marxist writings on class within anthropology. More recent work, such as that by Brackette Williams or Donna Goldstein, tends rather to tackle class while in the pursuit of other themes, commonly race, ethnicity, sexuality, and gender.

SOCIETIES, COMPLEX

Complex society refers to societies with states and social classes. Three kinds of complexity are involved: there are socially and culturally differentiated and unequal groups; social segments have specialized activities and roles; and these societies are geographically complex, with unequal exchange between specialized regions. The term "complex society" is typical social scientific jargon, being both dull and unfamiliar. However, its usage is justified. Civilization, an alternative term, has biased connotations, favoring the written and artistic products of upper classes. States and class society are terms that point to only the political and economic aspects, respectively, of the whole.

Complex society rests on a contrast with small-scale or simple societies. In the latter, people have equitable access to resources and enact similar activities, with differentiation deriving only from age, sex, and personal qualities. Foundational theories (e.g., Herbert Spencer's) emphasized the "evolution" from uniformity to differentiation, and anthropologists focused on the simple and uniform end. The topic of complex societies thus challenges standard anthropological approaches (such as fieldwork in small,

bounded places) and concepts (such as singular, integrated culture).

Complex society has been a central concern of archaeology, especially the causes of change from non-state to state organization, and the economic, social, and cultural changes accompanying that transition. Leslie White's unilinear evolutionary formulation of increasing energy control was influential, but probably the most influential argument was Julian Steward's case (derived from Karl Wittfogel) for the centralized management of irrigation. This argument quickly encountered empirical objections (rather sophisticated irrigation systems can be managed under local control, meaning that centralized power is not needed), but the real impact of Steward was his careful comparison of the rise of complex societies in diverse world regions.

After Steward and White, much effort was devoted to formulating types of cultures and identifying single causes ("prime movers") of change from one stage to the next. Morton Fried postulated population growth as a prime mover, while Robert Carneiro proposed political-geographical circumscription. In this elegant model, societies remain small in scale by hiving off identical units until they reach a point of closure by other, similar units; at that point, political centralization begins. However, recent scholarship has changed focus.

First, this work moves away from prime movers toward multi-causal, interactive models of change. Second, it explores, through systems theory, the morphology and dynamics of complexity itself. Third, the dividing lines between simple and complex are no longer straightforward matters of correct typology and classification, let alone unidirectional evolution. Instead, social formations move dynamically between different levels of centralization and specialization over time and space. All these trends are illustrated by recent studies of ancient core-periphery relations. Complex societies emerge from and create unequal exchange relationships between geographic zones that are politically powerful, socially hierarchical, and densely populated (and thus appear to be core "complex societies") and other zones that are politically dependent, less hierarchical, and more sparsely populated (and thus appear to be "simpler societies"), but which produce valued raw materials for the core.

Shifting focus from simple to complex societies has particularly challenged cultural anthropology. The biases in favor of functioning social wholes (in British

and French anthropology) and singular, integrated cultures (in U.S. anthropology) do not fit the differentiation and unequal power characteristic of complex societies. Initial approaches—such as the study of “national character,” treating vast nations as if they had one typical personality—were not satisfactory. Community studies became widespread, but scholars quickly realized that single communities could not represent entire complex societies. Community studies were also biased by the anthropological predilection toward the rural, culturally distinctive, and seemingly least modern.

Steward and his students first responded to this challenge by envisioning complex societies in terms of levels of integration, that is, a nested hierarchy of local ethnographic parts forming larger regional and national wholes. Though certainly an improvement, such levels were more an abstract architecture of units than the study of relations between them. Steward’s students Sidney Mintz and Eric Wolf next explored the synapses between social segments, such as regional market systems and labor and resource exchanges between great landed estates and peasant communities. They also introduced the idea, to become influential subsequently, of major historical processes—such as world capitalism—unifying apparently differentiated places across space. Meanwhile, ethnographies of community types crucial to complex societies became more common in anthropology, such as plantations and cities.

By the 1960s and 1970s, it became clear to cultural anthropologists that the diverse range of modern ethnographic cases, whether simple or complex in their local manifestations, formed one unified world system organized around differentiated and unequal but interrelated roles in the capitalist economy. Furthermore, the world had many different processes of interaction, ideas as well as commodities. This favors methods—multi-sited ethnography—suited to processes with multiple local manifestations.

Anthropology’s “integrated, meaningful whole” concept of culture could not survive confrontation with this degree of social complexity and processuality. The initial conceptualization was that of subcultures, that is, complex societies were assemblages of group or regional/local cultural variants. The subculture concept in practice was flawed, since it was applied to subordinate groups (e.g., African Americans), while dominant groups (e.g., Euro Americans) simply had “culture,” which remained

largely unexamined anyway. Recent work, especially by the Italian Marxist Antonio Gramsci, instead draws on theories that emphasize cultural construction over time within a web of power relations to examine the making of internally differentiated but coordinated cultural wholes, such as nations. Claudio Lomnitz, for example, built a complex model of Mexican society around communication among disparate and unequal actors in local, political, and national arenas, by documenting political rituals in public settings.

State and class societies may be organizationally complex, but the processes orchestrating them involve radical simplifications of cultural content, most notably commoditization. The global market in sugar described by Sidney Mintz brought about monocrop cultivation and drastic simplifications in diet, and similar arguments can be made for oil, the driving force of the contemporary world. Meanwhile, supposedly “simple” societies have distributed among their members, in a horizontal, cellular fashion rather than a hierarchical one, immensely complex knowledge of plants, animals, and the spiritual world.

SOCIETIES, EGALITARIAN

All human societies have mechanisms that maintain social order so that decisions can be made, disputes resolved, and behavior regulated. In large states this is clearly apparent in the political and judicial structures developed for such purposes. However, in many

societies these formal mechanisms seem nonexistent. In classic anthropological discourse, these egalitarian societies are “tribes without rulers.”

Egalitarian societies are those in which little or no formal structure exists that places authority and power into the hands of certain individuals or groups on the basis of hereditary right or positions of authority. Indeed, in egalitarian societies there are no positions of authority. Every man, and in some societies woman, has an equal say in matters concerning the group and participates fully in decision making. No person can exert authority over another, and there are no avenues for individuals to acquire privileged positions that might provide them with unequal power over others.

It is easy to see how shared decision making in small band societies can be managed without too much difficulty. Many food-gathering societies spend most of their time living in family units small enough to manage their subsistence activities so that group dynamics can be jointly managed by consensus. The food-gathering bands of the Kalahari Desert and Australia are classic examples of this kind of egalitarian society.

Although it might be assumed that as a cohabiting population increases more formal mechanisms would need to be initiated to manage group interaction, this is not necessarily the case. There are dense populations that have informal, egalitarian relationships between individuals. In classic anthropological literature, these are found in horticultural and pastoralist societies located in Melanesia, Southeast Asia, and Africa.

Perhaps the best known of these are the “big man” societies of Melanesia. In these essentially egalitarian societies, some individuals are personally ambitious, setting out in their careers to garner more influence and prestige than other members of the group. These men display unique qualities of leadership and have persuasive oratorical and entrepreneurial skills. By manipulating relationships that give them greater access to wealth, these men are able to exert more influence over the members of the group than anyone else. However, these men have no authority and no power to make people do what they wish. They can only “lead” by persuasion. At any time, people can withdraw their support and the big man topples and another takes his place.

The existence of egalitarian societies might suggest that relations between all members of the society are

based upon equality. However, one must take a closer look at the realities. There are extremely few societies where all members—men, women, and children—have an equal say in decisions made on behalf of the group. The Batek of Malaysia provides an example. The majority of egalitarian societies maintain inequitable relations between certain classes of its members. Even in those societies of the Kalahari Desert and Australia where equality between individuals is most apparent, women and the uninitiated have an inequitable part to play in matters concerning marriage, for example. When anthropologists talk about egalitarian societies, they are generally referring to the relations between men.

SOCIETIES, RANK

How people are socially situated in any given society vis-à-vis others is more than simply a political question, it is an issue of people’s relative “value” as this is determined by the members of a community. In anthropology, issues of rank are often found in chapters concerning political processes. While the consequences of rank invariably filter into the political sphere, the basis for rank may find its roots outside it. In the political sphere, rank clearly identifies the hierarchical relationships of people operating within positions of power and authority. However, the basis upon which these relationships rest may be found within the belief systems of the people.

Rank commonly refers to the social position of people in societies recognizing social hierarchies of one kind or another. These societies are organized according to principles determining the relative value of certain groups or individuals over others. This often has implications for people's relative access to resources, opportunity, positions of power, and authority within the political or religious sectors. While all societies have some level of status differential where age, gender, and other individual characteristics are markers of relative value, those societies recognizing hereditary rank have more formalized means of attributing value, affording individuals with relative status.

The Trobriand Islands located in the Milne Bay Province of Papua New Guinea offer a classic anthropological example of hereditary rank established in the mythological origins of the four clans. Each of the clans has relative status to each other, with the Tabalu clan holding the highest rank. As well as each clan being ranked relative to the other three, the clan is made up of subclans that are likewise ranked. Not only does the highest-ranking chief come from the Tabalu clan, but he also comes from the highest-ranking subclan.

The indigenous people of the Hawaiian Islands had a more complex social system based on hereditary rank and classes. In Hawaiian society, people were born into social classes as inferiors, commoners, or nobles. Nobles were hierarchically ranked according to traced descent from the gods, with those more closely linked to godly descent occupying the higher echelons of the society and forming the elite classes of paramount chiefs. The whole system was ranked according to formal rules of hierarchical descent. The ruling elite maintained religious and secular control over the rest of the population, the latter providing tribute in the form of food and other wealth items.

The previous examples illustrate what anthropologists have classified as “ascribed rank,” where individuals and groups find themselves in relative positions of rank by virtue of being born into socially established positions of hierarchy. In other societies, such as the “big man” political systems of Melanesia, men establish their rank by “achieving” status for themselves. In these societies, there is no formal, well-established hierarchical structuring of groups, no positions of rank to be filled. Instead, all groups enjoy relative equality with each other and group consensus is sought in decision making. However, there are some men who seek more status by manipulating relationships of exchange and marriage to build up

positions of status. While achieved status gives them temporary “rank” in that people look to them for leadership and direction, their positions are extremely tenuous. They have no official status. Their status is achieved.

SOCIETIES, SECRET

Identifying the boundaries that circumscribe social groupings can present challenges, not only for anthropologists but also for those people living within the social groupings. There was a time in anthropological investigations where this did not seem to be a significant issue, when groups on the ground and living in relative communication with each other could easily appear as discrete social entities. It was in the latter part of the 20th century that the complexities of group interconnection became more apparent, with an increasing understanding of local and regional social dynamics. These regional and intraregional relationships necessitate that all social groupings define some kind of exclusivity that enables distinctions between and within the sentient social groups; “We are the people who do not eat human flesh” or “We are the people who believe. . .”

All social groupings, whether these are large-scale distinctions between societies or more esoteric divisions within social entities, are delineated by constructed boundaries defining difference. Often these differences are measured by the degrees of knowledge held by an “in-group” and considered distinct from the knowledge held by the “out-group.” Secret societies are so defined by the use of some aspect of secrecy as an indicator of exclusivity. For example, medical

Source: Courtesy, Library of Congress.

practitioners, while not strictly speaking a secret society, might be likened to one by their use of technical language far beyond the comprehension of the majority of their clients. Furthermore, medical practitioners must undergo strictly maintained initiation and periods of hardship through long internships so as to be accepted into the profession. We tend not to consider such Western professions as secret societies because the knowledge they hold is theoretically available to all. But for most, this is not a reality given the exclusive conditions that enable only some to be admitted into the preliminary initiation and transferral of knowledge at university level. More traditional thinking about secret societies concerns groups who imagine that they hold secret knowledge or perform secret ceremonies exclusive to that group. They form a defined boundary around themselves that is recognized by both insiders and outsiders. Extensive initiations often accompany an individual's acceptance into the group, marking a transition from being an outsider to an insider. In Western societies, cloistered religious communities provide an example.

Imagery is used in many forms to represent the secret nature of these groups. This imagery can be in the form of sounds or words (Wicca magical texts), music (secret flutes identify men's secret societies in parts of Papua New Guinea), masks and costumes (Poro and Sande secret societies of West Africa), or art (bark paintings of Northeast Arnhem Land, Australia). While these artefacts may be the visual or auditory means of representing these groups, a more significant aspect of secret societies is the transformation from being an outsider to an insider. Initiations into a secret society are often accompanied by significant payments to the gatekeepers. The initiations, themselves, can be extensive and punishing. During the periods of initiation, esoteric knowledge is gradually revealed to the initiates, who gain by degrees the secret knowledge held by the group. Some of the most famous anthropological examples of secret societies are the Poro and Sande societies prevailing in West African social groups, the secret societies of Papua New Guinea, and the diversity of secret/sacred knowledge held by Aboriginal Australians in a variety of social groupings.

SECRET SOCIETIES

Secret societies are extremely varied in the forms they take and their members can be linked together by community service, religious values, political agendas, and economic interests. Groups as diverse as the Muslim Brotherhood, Freemasons,

Rosicrucians, the Mafia, Elks, Moose, and Chinese triads can all be considered secret societies. In spite of their differences, these groups all share a type of organization that keeps secret knowledge from nonmembers. They all also offer their members a system of mutual aid and assistance. Because of this closely knit structure, membership is limited to people of a particular group, which is defined by categories such as age, gender, social status, ethnicity, political, or religious faith.

A halo of mystery has always enveloped the existence of secret societies. This sense of mystery is often achieved through a recourse to religious or philosophical symbols or rituals. The significance of these are only known to members, so that some rituals become forms of initiation. Because of this spiritual dimension, members feel invested by a sense of responsibility and authority. They are united by the purposes that they have to accomplish. The mystery surrounding secret societies is enhanced also by the fact that only members and, sometimes, only members of a certain status have full knowledge of the society's actions. Because of their organization, secret societies often become separate entities that can act to legitimate or overthrow the larger political system, especially in countries where governments are unable to control social dynamics fully. For example, anthropologists who have studied Poro (male) and Sande (female) secret societies in Liberia have pointed out their role of assistance to the government and stimulation to social change. The methods of these societies, however, have also been criticized as violent and as perpetrating inhuman tribal practices such as female genital mutilation.

The role of secret societies in the political life of developed countries is still more ambiguous. Important politicians such as American presidents George H.W. and George W. Bush and Italian Prime Minister Silvio Berlusconi have been part of secret societies. Several plans made by secret societies and corrupted intelligence agencies to overthrow democratic governments have been uncovered in several countries. This has led to a certain degree of suspicion from the larger society toward secret societies.

— Luca Prono

SOCIOBIOLOGY

Sociobiology is the systematic study of animal and human social behavior from the perspective of biological evolution, especially from the gene's point of view. An evolutionary approach to social behavior means to focus not on the proximate mechanisms (e.g., biochemical or humoral) that cause a particular behavior, but mostly (even exclusively, if possible) on so-called ultimate explanations, which aim to discover why proximate behavioral machineries work that way and how they evolved as a result of natural selection.

The term sociobiology was coined by Harvard entomologist Edward O. Wilson in his book *Sociobiology: The New Synthesis* (1975). His bulky book is a valuable summary and synthesis of several new ideas about the evolution of animal societies developed in the U.S. and Britain between the mid-1960s and the mid-1970s. However, in the last chapter of his book, Wilson extended this newly emerging evolutionary approach to the social behavior of human species, which became the main reason for strong criticism of all sociobiology.

Most cultural and social anthropologists, sociologists, and philosophers felt and still feel insulted by the reduction of human behavior to what they called a biological and genetic determinism, which is, however, not a goal of sociobiology. They perceive sociobiology to be a modern renewal of Social Darwinism with all its objectionable consequences—justification of racial, economic, and gender inequalities—and a new pseudo-scientific apology for political conservatism. As a consequence of massive—and mostly unfair—criticism, sociobiology soon became an intellectual dirty word in academic circles. Today, the term sociobiology is seldom used by evolutionary biologists; however, sociobiological research is not dead. Sociobiological principles have become crucial parts of contemporary ethology, behavioral ecology, and evolutionary psychology.

Sociobiology has had a major impact on the conceptual revolution toward a gene-centered view of evolution. This paradigm shift in evolutionary theory was ingeniously and widely popularized by Oxford zoologist Richard Dawkins in his book *The Selfish Gene* (1976).

Altruism is often thought to be a distinguished mark of civilized human behavior, a quintessence of

humanism that differentiates us from the brute and selfish world of animals as well as from barbaric Hobbesian human societies. In this popular scenario, the natural human default is selfishness; humans are born as self-oriented, egoistic beings who have to learn as they grow through enculturation and socialization how to behave altruistically and prosocially. However, this view of Nature as “red in tooth and claw,” which seems to be so well described in terms of “struggle for survival,” is seriously undermined by the existence of altruistic behavior among animals.

A generally accepted explanation of animal altruism until the 1970s was group selection theory, which states that evolution works for the benefit of species rather than individual organisms. For example, through natural selection, organisms can develop special mechanisms (e.g., physiological, behavioral) that sense population density and can put limits on individual reproduction in order to prevent population overgrowth. By those evolved mechanisms, short-term individual and selfish reproduction interests are counterselected in favor of long-term population survival. Group selection theory has been refuted on theoretical as well as on empirical grounds, and contemporary biologists consider it to be a fallacy. Any population of reproductive altruists would be extremely vulnerable to spontaneous selfish mutants that are not genetically disposed to control their reproduction. A population of genetically determined altruists would then quickly turn to a population of genetically determined self-seekers. Group selection is not impossible, but is very rare.

However, from a classical Darwinian point of view there is nothing more altruistic than sacrificing one's own reproduction in favor of others. One can easily see why the Darwinian evolutionary parameter “fitness” is, in fact, misleading if we understand it as “survival success.” It is not survival itself that counts in evolution but producing offspring. Evolutionary biologists now prefer to talk about “reproductive success” instead of “fitness.” But then, how can sterile castes of social insects evolve by natural selection? Darwin was aware of the paradox of sterility in social insects like ants, bees, and termites, and he mentioned it in *The Origin of Species* (1859) as “by far the most serious special difficulty which my theory has encountered.”

It was William D. Hamilton (1936–2000), a PhD student at London University, who recognized the pivotal role of altruism and its extreme form, sterility, in evolutionary theory. In 1964 he published

a mathematical theory of a new concept, “inclusive fitness” (later known as the theory of kin selection), which became a Holy Grail of sociobiology. It was generally known that fitness parameters actually represent the number of copies of a gene passed to the next generation, rather than the number of offspring produced by parents. But only Hamilton understood that copies of genes are multiplied not only directly, passing from parents to their own offspring, but also indirectly (with a probability that depends on degree of relatedness) through offspring of their relatives, and this indirect reproductive gain has to be included in a fitness parameter. Hamilton discovered a mathematical formula (known as Hamilton's rule), which shows that from a gene's point of view, there are conditions under which a gene responsible for altruistic behavior will evolve: the reproductive benefit to the recipient of the altruistic act multiplied by degree of relatedness has to be higher than the reproductive cost to the altruistic individual. Hamilton is now considered by some to be the greatest evolutionist of the second half of the 20th century since Darwin.

It is estimated that eusocial species with sterile castes, like ants and bees, appeared several times independently during Hymenoptera evolution. Hamilton's rule offers an explanation for this evolutionary tendency. Due to a special haplo-diploid reproduction of Hymenoptera (males are haploid because they come from unfertilized eggs, females are diploid), the coefficient of relatedness between female worker bees is 0.75, but between bee mother (queen) and her offspring only 0.50. It follows, according to Hamilton's rule, that from a gene's perspective there will be more copies of a gene produced if female workers support the reproduction of their mother and take care of their sisters instead of having their own offspring (all other things being equal).

Based on Hamilton's rule, Richard Alexander, a zoologist from Michigan University, predicted the existence of a eusocial mammal living in a similar way as social insects, and this animal species was in fact later discovered on the Horn of Africa. Naked mole rats (*Heterocephalus glaber*) built subterranean tunnel systems inhabited by a colony of 70–80 members. There is only a single reproductive female, a queen, which mates only with one to three males who are brothers. Due to systematic inbreeding, the coefficient of relatedness among members of a colony is as high as 0.85.

A gene-centered perspective is able to explain unexpected altruistic behavior, and it is also able to

elucidate unexpected antagonistic behavior, such as between parents and their offspring. It was Robert Trivers, then at Harvard University, who pointed in 1974 to a parent-offspring conflict over parental investment. An individual offspring is more closely related to itself than to its siblings and parents; therefore, a child is selected to demand more parental investment for itself than for its siblings, which is more than a parent is selected to offer, since parents are equally related to all their offspring. Trivers ingeniously recognized that such fitness conflict can be behind offspring manipulative behavior to compel more care than it is in the interest of parents to give. For example, sending false signals to the parents that the offspring is younger than it really is, or performing a temper tantrum behavior (familiar not only to our own species, but also to young pelicans, baboons, or chimpanzees) in order to solicit extra parental care.

One of the most common objections to sociobiology is that there are many examples of altruistic behavior between genetically nonrelated individuals, even between members of phylogenetically distant species, as in many cases of symbiosis, which obviously cannot be explained by kin selection. Robert Trivers proposed a theory of reciprocal altruism. The idea is very simple: an individual can be selected for altruistic behavior to a genetically unrelated individual if it is reciprocated later. The major problem is that this system is vulnerable to cheaters and free-loaders. However, using a game theory approach (iterated Prisoner's Dilemma game) and computer simulations, he was able to demonstrate that under specific conditions, which can be met in nature, various cooperative strategies can be selected.

Sociobiology has been “dissolved” into modern ethology, behavioral ecology, and recently into evolutionary psychology. During the past three decades, scientists engaging in sociobiological research continually have been sharpening their conceptual thinking, improving their methodology in a way that cannot be easily accused of creating only evolutionary “just-so-stories,” and they have successfully accumulated empirical data in support of sociobiological principles.

SOCIOLINGUISTICS

Of the many fields of language study, sociolinguistics is one that provides understanding regarding the choices that people make to communicate with one another, to form communities, and to establish their personal identities in society. Sociolinguistics is a field in which communication, especially oral communication, is observed and documented in order to discover not only the nature and kinds of information that humans attempt to share but the manner in which they share it. Unlike the work of formal linguistics that strives to classify and describe the component forms of language, sociolinguistics attempts to characterize the ways that people use language in specific situations in a social context.

The Science of Linguistics and the Birth of Sociolinguistics

In the 19th century, the study of human language was an area of interest for philosophers and classical philologists. Much of the theorizing about language was done by researchers from Western Europe, and they took interest in comparative studies of language history relying upon the writings of the ancient philosophers, especially Socrates and Plato. As societies developed, and more and more nations enabled the education of their peoples in literacy, there was a renewed respect for the classical languages and the works of the philosophers who addressed language issues. Thus, the philologists continued to be driven to compare and contrast language as history, using their gleanings from ancient philosophy and literature. Their study was one in which the lives of the people

who used language were considered secondary to understanding the actual language characteristics themselves. However, studies in anthropology, particularly those of Charles Darwin, sparked curiosity for finding different approaches to understanding the role that language plays in the development of peoples.

Ferdinand de Saussure

Language researchers acknowledge the theories of a Swiss linguist, Ferdinand de Saussure (1857–1913), as having provided a revolution in thought regarding the study of languages that led to the growth of linguistics as a science and the development of the field of sociolinguistics in the 20th century. Although he did not write down his ideas in any lengthy pieces of text, the dissemination of his class lectures by his students after he died enabled linguists to take a look at the manner in which they had been approaching language study up to the end of the 19th century and to consider what Saussure thought was most important: language is a means for the communication of thoughts and ideas by individuals who belong to communities in which they developed their language; individuals gain an understanding of reality through social use of the language they know.

The *Course in General Linguistics* of Saussure continues to be read and cited to this day, and some linguists state that because of Saussure a tremendous shift, a Copernican revolution, occurred in the study of language and society. Saussure's theories caused the end of what was termed a Socratic tradition of linguistic thought. Instead of framing the study of language as governed by a set of rules that are applied to some word or statement all by itself, Saussure emphasized that language was a structured system that could be understood scientifically by watching how individuals in a community used it at given points in time, synchronically. Linguists have classified the Saussurean approach to language as holistic and one of *structuralism*.

Language Evolution and Change

Saussure was only two years old when Charles Darwin wrote *The Origin of Species*, and linguists in the early 20th century commented that Saussure's position about language change and evolution showed that he was aware of Darwin's theories. Saussure observed that it was important to understand the history of

how some human languages evolve while others decay, given the nature of language for communication within societies and communities. He called it a *natural sequence*, referring to his view of looking at language change historically, diachronically. Therefore, Saussure's theory included a dimension of studying the language use of individuals in society (synchronic) and a dimension of studying language change in history (diachronic).

The Growth of Sociolinguistics

Although the seeds of sociolinguistics were planted at the turn of the 20th century, the term was not used until the early 1950s. In the 1960s and 1970s, there was a considerable body of work undertaken by individuals that might be considered the godparents of the field. Although many of the researchers were from cultures in the West, individuals from developing nations throughout the world began studying sociolinguistics for the sake of understanding their peoples and the ways that language use influenced the growth of their nations.

Sociolinguistic research has covered a broad range of topics including: the study of politeness forms (e.g., God bless you; hello; bye-bye), high and low languages (e.g., speech used in the courtroom and speech used at home), the cultural interpretation of silence in Native American tribes, nonstandard English, language use and social status, turn-taking in conversation, pidgins and creoles, gender differences in speech, and language dialects. In the latter decades of the 20th century, social uses of language became a major curiosity in popular American culture as Deborah Tannen published her research about communication between the genders and communication in the workplace.

Sociolinguistics as a Process

Those who call themselves sociolinguists are researchers who want to know how individuals communicate in particular contexts such as the political arena, in sports, in Web logs, or in courts of law. A second important role, shared by another group of linguists in the field of anthropological linguistics, is to characterize how languages develop and change, and how and why some languages become extinct. This role is one that depends upon learning about the structure of societies and the changes that take place as societies interact with each other.

Scientists who are involved in sociolinguistic studies typically employ ethnographic research designs. Their research incorporates much fieldwork and the documentation of language behavior that helps to answer particular research questions. What characterizes an *ethnography of communication* is that the use of language in general is related to specific social and cultural values. Anthropologist Dell Hymes is considered the father of this approach to sociolinguistic research.

Studying Language Use

In the 1960s, Hymes was concerned that as linguists and anthropologists studied human characteristics, each of the groups was missing important areas that might explain aspects of culture and society. He thought that linguists were becoming too focused on describing language forms and structures, and he thought that anthropologists considered language as a secondary entity to getting answers about other things of cultural interest (e.g., about medicine and curing).

Hymes proposed that a paradigm such as one on the ethnography of speaking would help both groups of scientists to get a fuller picture of their areas of study. For example, Basso studied the use of speech and the refraining from speaking in Western Apache tribes of east-central Arizona. In his time with these Native Americans, he was able to document and interpret the decision-making processes that individuals used in their conversations by applying an ethnography of communication. He added to the growing body of sociolinguistic knowledge, calling attention to the differences in interactions where individuals judiciously decide when it is appropriate to speak and when silence is important. From Basso's engagements with members of the Apache tribes, he documented conversations for several social contexts including courtship and being with people who are sad. Basso saw that silence is an acceptable behavior in Apache culture and one that is never curtailed by any participating individual in particular collaborative settings. In this culture, a person is silent because he perceives his relationship to be ambiguous or unpredictable in that setting. Basso explains that knowledge of the positioning of silence can help inform research regarding conversational behaviors and tempos in other societies, and comparative studies would provide additional information to the field of sociolinguistics.

Speech Communities and Language Varieties

Sociolinguistics involves the study of individuals in settings of language exchange, and the environments in which individuals develop their communication abilities usually includes members of a society or group beyond that of the family. This social group is sometimes characterized as a *speech community*.

Crystal defines a speech community as a cluster of speakers that can be quite tiny or involve whole nations, or cross several nations in a common geographic area where there is a shared spoken language or *language variety*. In the latter case (i.e., the language variety), the group of individuals may use a particular system of communication within their native language that might be derived from common factors such as an occupation, a regional situation, or a social class. A variety might also be a distinctive language that has developed within a religious group, a formal or conversational group, or a scientific group, to name just a few examples.

Sociolinguistics is especially interested in the study of the social dynamics that are involved when there are language varieties in speech communities that might appear to cause the stratification of society, or might indicate a division between and among groups of individuals within the society. Other considerations include concern for conversational variation and linkage of language varieties among individuals due to differences in occupations, professions, or social context. The term *register* is used to describe the ways that individuals use language depending upon who is in the conversation group. For example, a store clerk performs her job by using a particular speech register to guide a customer to a clothing rack, but at the bus stop after work she converses with that customer quite differently. A CEO uses one register to speak to his managers at work and another register while attending a sporting event with them.

MacNeil and Cran provide an elaborate ethnographical mosaic that answers many questions regarding the dynamics of American English across the United States in a wide variety of speech communities. Popular comments and informal theories about the influences of media culture upon the American public seemed to predict that language was becoming homogeneous, that there is one, singular, American English, but these researchers discovered significant diversity, individual choice, and creativity.

For example, they comment on the role that the *Valspeak* of California has played in the common speech of teenagers and young adults across America; the possibilities for transmitting real speech patterns, dialects, and accents in new technology and the implications to human interactions with computer-generated speech and synthetic faces; the dominance of English and the loss of Spanish in the Mexican American community.

Diglossia

Beyond the study of language in a defined speech community, there are situations in which individuals might use more than one language variety in the same language across speech communities. This is an especially well-studied area of sociolinguistics. Ferguson is credited for calling attention to this dynamic, which he termed *diglossia*. In his classic article, he gives an example of the Christian Arabs in Baghdad who speak a variety of Christian Arabic when they are together and speak a more general form of Muslim Arabic when they are in a mixed group. What is interesting about diglossic situations is that the language varieties exist side by side, and may have been maintained over long periods of history, over several centuries. These language varieties are not merely stages on the way toward a more common form of language. They are distinct, persisting variations that are accepted forms within their speech communities.

Historically, some diglossic situations are characterized as high and low usages of speech and language. Although these variations are sometimes referred to as dialects, they differ from standard dialects because there may be grammatically complex differences between two diglossic varieties and not just differences in speech characteristics. This can be somewhat understood as a distinction between formal speech and a vernacular. In the case of China, for example, there are a great number of language varieties in existence with so many low varieties that they are sometimes characterized as separate languages.

As societies advance economically, enhance education, and promote literacy, and as communication increases among members of speech communities in the society, diglossic language varieties tend to disappear. In some societies, when the community becomes aware of the multiplicity of language varieties,

there are political discussions and movements to unify the language of the community and accept only one of the forms as the main language.

Pidgins and Creoles

A category of languages that is a source of considerable research by linguists, and especially by sociolinguists, includes pidgins and creoles. These are derivatives from interactions between groups of people with two very different languages, as in the case of French explorers trying to communicate with individuals in the Ivory Coast. Fasold explains that the role that pidgins play in revealing how human languages are created and evolve is particularly important for sociolinguistics but also requires characterization by formal linguists. As sociolinguists have characterized these two language varieties, other linguists have become curious in their own fields of study. These include studies of child language development, studies of nonstandard English, and studies of the innateness of language in human beings.

Sociolinguistic Horizons

Advances in media communication have helped to make people aware of societies other than their own that at one time received little recognition except from researchers. In the United States, from the date September 11, 2001, citizens have become accustomed to hearing and pronouncing the names of individuals from predominantly Muslim nations and learning about cultures in the Middle and Near East. There is a growing awareness around the world of how men and women live in countries in these regions and concern about political and economic change in countries that were seldom studied in detail in schools in the West. The tsunami disaster in Indonesia in December 2004 enabled societies around the world to connect and to try to understand the struggles of the affected nations in that part of the world. The field of sociolinguistics will continue to provide interpretations of the language interactions across the wide variety of existing social contexts, those that evolve in the 21st century.

SOCIOLOGY

Sociology is the systematic study of human behavior occurring in a social context. It seeks to understand how and why people act the way they do across an enormous variety of settings. Two major influences are acknowledged to affect human social behavior: (1) cultural factors such as values and norms and (2) structural factors such as the economic and political structures of society. Sociologists generally study human behavior in complex rather than small-scale societies.

Sociology is a relatively young discipline, arising out of the tumult of the Industrial Revolution in Europe beginning in the 18th century. The social organization of society was profoundly altered by the processes of industrialization and urbanization.

The term *sociology* was coined in 1822 by the French philosopher Auguste Comte (1798–1857), who was the first to suggest that society itself is an appropriate subject for scientific study. Many of the earliest intellectual influences on sociology also heavily influenced the field of anthropology, including Max Weber, Émile Durkheim, Karl Marx, and Herbert Spencer.

A unifying concept among all sociologists is the belief that society constrains the options and opportunities of all individuals to some degree. In Durkheim's (1858–1917) terms, “social facts,” the context in which people's lives are embedded, shape human behavior by defining the constraints and opportunities within which people must act. C. Wright Mills (1916–1962) argued that sociology allowed people to see their own personal troubles in the context of larger structural factors; he termed the ability to see this connection the “sociological imagination.”

Theoretical Perspectives

Sociology is characterized by the use of broad theories to guide research and to provide an explanatory framework for data gathered through systematic observation. The major theoretical perspectives are briefly described below.

Functionalism. Associated with the earliest sociologists such as Comte and Durkheim, functionalism takes as its basic assumption that society works as a system, where each part contributes to the well-being and smooth operation of the entire group. Each part has a function that contributes to the stability of the system. Social solidarity rests on shared values as well as shared culture. Social problems are typically seen as a result of reduced social solidarity, often as a result of rapid social change. Social change may originate outside the social system; for example, the Industrial Revolution and the rapid urbanization that followed created disequilibrium in society, the aftershocks of which are still being felt today. Functionalists are also sometimes referred to as “structural functionalists” because they analyze how the parts of society, or structures, fit together and how each part contributes to the stability of the whole, its function.

Conflict Theory. A macrolevel perspective like functionalism, conflict theory focuses on inequality in society. It begins with the assumption that society is made up of groups that compete for scarce resources. Resources may be seen as financial, political, or social, such as prestige or respect. Privileged groups try to maintain their advantages, less privileged groups try to increase their resources. Conflict theory originated in the work of German social thinker Karl Marx (1818–1883), who observed and wrote about the conditions suffered by workers in the factories in the early years of industrialization. He developed a theory of class conflict, arguing that there is a fundamental conflict between those who own the means of production, the capitalists, and the workers, who only own their own labor and thus must work for wages.

Symbolic Interactionism. The focus of symbolic interactionism is interpersonal communication and the subjective meanings created in small social settings. A microapproach, it stresses that people are active agents in creating meaning, not passive recipients of culture. The dramaturgical approach (Goffman) looks at how people present themselves to others in everyday life so as to make the best impression. He compared social interactions to a carefully

staged play, with actors playing roles on both the front and back stage. Social constructionists are interested in how individuals create society through interactions.

Feminist Theory. Developing with the second wave of the feminist movement in the 1960s and 1970s, feminist theory has two major tenets. First, gender matters must be addressed in theory and research. Second, it questions the assumptions of rational objectivity and value-free research that had prevailed in sociology since its earliest days. Feminists argue that gender inequality, often called “patriarchy,” is pervasive and exerts an influence on society equal to that of social class. While a great diversity exists among feminists regarding the causes and contributing factors of inequality, there is agreement that the origin is primarily structural rather than biological.

Methods of Sociology

Sociological research is based on scientific principles, not so different from those methods used by the hard sciences, in that the bases of nearly all social science research is observation and theory. Data are gathered systematically and analyzed within a theoretical framework that allows sense to be made from the mass of data collected, using one of several typical methods. Broadly speaking, sociological research can be described as either quantitative, meaning the collection and analysis of data that is numeric in nature, or that can be turned into numbers, and qualitative, or non-numeric data.

Survey Research. Perhaps the most common type of social science research methodology, surveys are widely used by pollsters and marketers as well and have become ubiquitous in modern life. Surveys can be conducted over the telephone, through the mail, in person, and increasingly over the Internet. Survey research involves the use of standard questions, asked of a group of people, referred to as respondents, who are believed to be representative of the population of interest, a sample. In large-scale surveys, the sample should be drawn using random selection techniques that increase the likelihood that the sample will be representative of the larger population of interest.

Field Research. Observing people in their natural surroundings is a useful way of obtaining rich, detailed, and nuanced information, especially regarding how people actually behave, rather than how they say they behave. One of the many challenges of field

research is systematically collecting and organizing the wealth of information that goes on in a natural setting. Data are often collected through the use of unstructured interviews, which are then transcribed and analyzed for patterns and insights.

Participant Observation. Like field research, participant observation occurs in natural settings where the researcher engages with his or her research subjects. By more actively participating in their subjects’ lives, for example, by living and working among the population of interest, the researchers gain an understanding of reality from their point of view.

Experiments. Elements of classical experimental design include random assignment of subjects to the control and experimental group; pretesting of all subjects on the dependent, or outcome, variable; administration of the intervention, or independent variable; and a posttest to measure change in the dependent variable. The hallmark of experimental design is control: the research controls all (or virtually all) extraneous variables in order to focus on the effects of the variable of interest. Sociological research is often not amenable to laboratory experiments, and so often experimental conditions are approximated in the field. Natural experiments, for example, take advantage of change occurring in the real world such as a new law; data from before the change were introduced and afterward are compared in order to assess the effect of the change.

Topics

The topics of sociology include all aspects of human behavior and experience. Topics can be broadly categorized into social processes, the mechanics of human interaction and development; inequality; the major institutions that organize social life; and social change. Each of these broad categories is further developed below.

Social Processes

Culture, the sum of shared ideas, practices, and material objects that people have created, allow humans to adapt to and thrive in any environment. Culture is learned, primarily through language, and acquired through the process of socialization.

Socialization is the process by which individuals acquire self-identity and the skills needed for survival in society. It is essential for survival and development; children reared alone never develop the skills to live

productive, independent lives. Socialization is a life-long process as we take on new roles throughout the life course. Sociologists acknowledge the contributions of psychologists to the understanding of human development, but focus their research and theory on the role of interactions with others in the creation of a self-concept. We gain information about ourselves through interactions with others and through imagining how others see us. Agents of socialization include important significant others, such as family and peers, and institutions, such as schools and the mass media.

Interaction, social intercourse, is a microlevel process that relies on shared meaning among the participants. Members of a society or subculture share norms and an interaction order that regulates social situations. Sociologists operating within the symbolic interactionist perspective argue that reality is socially constructed; that is, our perception of reality is largely shaped by the subjective meaning we assign an experience.

Inequality

Deviance and Crime. Sociologists have always taken a keen interest in crime and deviance, making some of their most significant and well-known contributions in this area. Durkheim, in the functionalist tradition, held that deviance often operates to increase social cohesion as societies pull together against perceived deviants. Defining what is deviant or outside the pale helps societies define their values and what they stand for. Thus, most sociologists believe that definitions of deviance and crime vary across societies. From a conflict perspective, powerful groups in society define what is deviant in order to control the behavior of the less powerful.

Stratification. All societies are marked by some form of social stratification, the organization of society into levels, although the most small-scale societies are generally only stratified by age and gender. The different layers are known as classes, and labels such as upper, middle, and lower class are used to describe the various levels. While classes may be defined by their economic conditions—Marx classified classes by their relation to the means of production, or economic status—there are noneconomic dimensions of class as well. Max Weber pointed out that class is not based on money alone but is also based on power and prestige. Members of different classes advertise their rank by displays of material and

symbolic culture, which are also important markers of class.

Race and Ethnicity. Sociologists hold that race and ethnicity are socially constructed ideas, used to distinguish people based on perceived physical or cultural differences. Race more than ethnicity is often a master status, an identity that takes precedence over all other identities or statuses a person holds. Minority racial or ethnic status has profound consequences for people, affecting their life chances in virtually all areas.

Gender and Sexuality. Gender is one of the most influential and pervasive forces shaping our lives. The dominant gender ideology is patriarchal in that men, masculinity, and masculine attributes are more valued in society than women and female characteristics and values. Children are socialized into gender identity through various agents of socialization such as the family, media, peers, and schools. Significant debate occurs over the relative strength of these different agents and the degree to which individuals are able to shape their own gender image, as well as over the causes of persistent inequality in the labor market. Women have increased their level of education and labor force participation rate significantly but still lag behind men in terms of income and opportunities.

Institutions

An institution, to a sociologist, is a form of organization that performs basic functions in a society. They are supported by social norms of the society and are slow to change.

Work and the Economy. The truly major changes in the world of work occurred around 10,000 years ago with the agricultural revolution, the consequences of which are that most people eventually gave up hunting and gathering for a life of agriculture or raising domesticated animals. Then sometime in the 18th century, the Industrial Revolution ushered in a new era of work organized around the ability to mass-produce goods for the market. Some have argued that we are experiencing a third revolution characterized by service occupations and high technology.

Government and Politics. Politics is the arena of power relations, the social institution through which power is acquired and used by people and groups. Government is a formal organization that is responsible for regulating relationships among members of a society and between a society and societies outside its borders. Political sociologists primarily focus on how

the political arena and its actors are intertwined with other social institutions such as the media, economy, religion, and education.

Families. The traditional nuclear family in the United States consists of a mother, father, and at least one child. Today less than one quarter of all households are traditionally structured with a stay-at-home wife and children under age 18. Family diversity has been increasing for many reasons, one of which is the fact that many of the functions once performed by families have been taken over by other institutions, including education, health care, defense, and religion. As people live longer and are more invested in their own happiness, the divorce rate has increased, although it has now stabilized.

Religion. The sociological study of religion looks at the visible and knowable aspects of religion, such as individual beliefs and practices, and the actions and organizational structure of religious groups and institutions. How are individuals socialized into religious communities? What is the nature and source of conflicts between different religions or between religious and secular groups in society? What is the effect of religious belief or identity on individuals' actions in other aspects of their lives? These are the types of questions sociologists of religion strive to answer.

Education is the social institution responsible for the transmission of knowledge, skills, and cultural values, enhancing social stability and also facilitating social change. Education begins at birth, with socialization within the family, but in modern industrial society formal education lasts into adulthood as young people must master an enormous body of knowledge to prepare for careers. Functionalists see education as promoting social solidarity and stability in society, whereas a conflict perspective notes the contributions of formal education to the reproduction of class inequality.

The Mass Media. The media, operating through the newspapers, television, radio, and movies, are significant agents of socialization in today's society. The media both reflect the concerns and issues of society and help shape cultural norms and values. Interactionists look at the way media influences society, whereas conflict theorists focus on who controls the media and this information in society.

Health and Health Care. Health, health care, and disability are major concerns not only for individuals but for societies as well. Paying for health care is a major expenditure for governments and employers.

People have control over their health through lifestyle factors, although social class, race, and gender influence health outcomes significantly.

Social Change

Population. Demography is the study of population size, composition, and distribution. Demography underlies many other areas of sociology because demographic variables such as age, gender, race, and population size, and growth rates affect many other social processes and aspects of social life. Changes in populations occur as a result of three processes: fertility, mortality, and migration.

Urbanization. Although cities have existed for thousands of years, up until 200 years ago no more than 3% of the world's population lived in cities. Today that figure is almost 50%. By 2050 it is estimated that two out of every three people will live in an urban area. Urban sociologists look at the evolution of the urban form, the experience of urban living, populations and groups living in and struggling for control of urban space, and many issues surrounding urban life, including race, gender, poverty, crime, urban economics, and the interaction between globalization and urbanization.

Collective Action and Social Movements. The history of modern, urban, industrial, and postindustrial society is increasingly the history of social movements. Social movements are involved in nationalism and movements toward independence and the increase in demands for equal treatment by disadvantaged groups across the globe. Social problems are typically recognized and addressed by social movements before they are tackled by governments.

The Future of Sociology

Sociology continues to be a vibrant discipline, continuing to grow and adapt to the changing needs of each generation. While in the past there was a significant divide between quantitative and qualitative sociologists, there is recognition that not only does each side make important contributions to understanding social life and processes, but it is also useful for researchers working in multiple traditions to collaborate. Large-scale survey research projects often now include a smaller qualitative component. Other areas that are expanding are examination of the role of technology and the Internet in social life.

The word sorcery usually means some sort of individual manipulation of supernatural forces to harm another person or to enrich the self at the expense of another, and in this sense belief in it seems to be absolutely universal. The English word derives from the Latin *sort-*, *sors* (“lots”), as in *sortilege*, to decide by the random fall of certain designated objects. This was a common method of divination in the classical world, which anyone could learn to perform but which was widely considered to be a human intrusion into divine business; hence, it was frequently forbidden under both ecclesiastical and civil law. This is especially true in the Judeo-Christian tradition. But the term sorcery came to refer to a great many “occult” dealings that were potentially dangerous. Often where it appears, the term is not defined, and its various possible meanings may have very different conceptual bases, and so the student must take care to ascertain exactly what is meant.

Sorcery can have any of the many meanings of magic or witchcraft. It is often used as synonymous with shamanism. It can mean any of the “occult” dabblings and traffickings condemned in the Bible, including conjuring of spirits and any of various methods of divination; it is the most frequent English gloss for the Hebrew *kishuf* or *kishef* (*mechashefa*, a female practitioner of *kishef*, was famously translated

as “witch” in the King James Version of 1611, thereby constructing that terrible commandment in Exodus 22:18: “Thou shalt not suffer a witch to live.”) Sorcery generally has a negative connotation, as in “black magic,” but not always; sometimes it refers to any individual efforts at manipulating the supernatural for personal benefit. Even within anthropology there is not uniform agreement on its appropriate usage. The following discussion will survey the most common meanings of sorcery by anthropologists, spirit invocation and command and harmful magic, and will consider some defenses against sorcery, remedies for misfortune caused by it, and anthropological explanations for this apparently dysfunctional phenomenon.

Sorcery in Anthropology

E. E. Evans-Pritchard in his famous work, *Witchcraft, Oracles and Magic among the Azande* (1937), is credited for having clarified the distinction between sorcery and witchcraft that most anthropologists recognize: sorcery is a learned magical practice requiring words, objects, and rituals, whereas witchcraft is an innate power that develops within some adults and operates mystically and sometimes without its bearer’s knowledge. The same distinction had been noted earlier in Melanesia by Reo Fortune in his *Sorcerers of Dobu* (1932), with the difference that on Dobu, mystical witchcraft is women’s unique capacity; sorcery is men’s. But Fortune’s report was not given credence until three decades later, and his pioneering place in the anthropology of sorcery and witchcraft was overshadowed by Evans-Pritchard.

Presumably the evil magician can demonstrate his techniques, and there are some ethnographic descriptions of how harmful magic is performed, but most descriptions of how sorcerers work are anecdotal, based in popular belief. One reason for the ethnographic difficulty in obtaining firsthand data is that sorcery is almost always covert. Sorcery manipulates the supernatural, which is always dangerous, and it is antisocial, so it is everywhere forbidden, even illegal; hence, it is clandestine, deeply feared, and discussed reluctantly and furtively, and it is more suspected than demonstrated in society. And some of the sorcerer’s alleged techniques involve invocation and command of spirits, or fantastic animal familiars, or mystical powers, and are impossible to verify. Worldwide, sorcerers are far more often men than

Source: © iStockphoto/Andreas Vitting.

women. The most likely sorcerers are people who have legitimately learned how to exploit natural and supernatural powers without harm to themselves, so it is assumed that they can use those same powers for antisocial purposes, for their own purposes, or for hire to others such as priests or shamans and skilled herbalists or other types of healers. Or, it is assumed that ordinary people can learn the techniques of sorcery under the tutelage of a skilled sorcerer.

Spirit Command

All over the world it is assumed that some people have perfected a technique of summoning and commanding spirits, and this is one widespread referent of the term sorcery. The idea of sorcery as spirit invocation and command is probably universal, and attack by a human-sent demon is an occasional diagnosis of some physical malady or social misfortune. But in most of the world's cultures, contact with spirits is extremely dangerous, and persons known to have had such contact cannot move freely in society. Spirit invocation is a common function of priests and a common beginning to any ritual of supplication, and shamans enter states of ecstatic trance in which their souls travel out to negotiate with spirits. But both of these respected practitioners must go through a ritual of desacralization before returning to society. And spirits are generally considered to be sentient and willful beings who are not docilely commanded and who, instead, might strike the presumptuous person or those near to him. James George Frazer in his great work, *The Golden Bough*, recognized these

problems in his discussion of spirit command as a magical act; he asserted that when spirits are commanded by magic, they respond passively and dumbly, like the forces of nature. This assertion may be widely unjustified. The widespread belief that people can command spirits and send them out on personal missions of evil remains a vague general fear, in the realm of conspiracy theory, only rarely associated with specific individuals.

Sorcery as Magic

Sorcerers may be assumed to have strengthened and energized their own measure of the personal power, similar to mana, that all cultures seem to believe in, and which is central to belief in magic. Or sorcerers' power may be bestowed by their spirit helpers, as among the Harney Valley Paiute of Oregon studied by Beatrice Whiting and reported in her classic work, *Paiute Sorcery* (1950). Apparently everywhere, sorcerers' power can be used to project things mystically through space. In Africa and the Americas, there are beliefs that sorcerers might dip a forefinger into some concoction and, by pointing it at their victims, project some malign influence—this belief is one rationalization for the avoidance of finger-pointing in social exchanges. (Would such sorcerers use their left hands for such nefarious acts? Sorcery is metaphorically referred to as “the work of the left hand” in Haiti and elsewhere, to distinguish this sinister act from honest, open worship of the gods, or from good magic.) In all regions of the world, illnesses might be caused by some foreign object or active agent mystically projected by a sorcerer into the body of the afflicted. In Africa and throughout the Americas, sorcerers send invisible darts, or needles, or bits of bone or tooth or other animal parts, or live animals, into their victims; among the Cebuano of the Philippines, as described by Richard Lieban, sorcerers' agents include seven-legged insects who eat away at the victim's insides and return at their master's command.

Perhaps the most common referent of the term sorcery is harmful or selfish magic, the sympathetic magic described by Frazer in *The Golden Bough*. Magic involves the manipulation and transfer of power through symbolic communication. Magic may

involve manipulation of natural forces, believed to energize all nature. Magic presumes a coherent universe in which all things are potentially interconnected; power can be sent along such connections by manipulations of symbols—objects, words, or actions that represent others and that take on and project their power through Frazer's classic principles of similarity or contact. The natural order of things is good and open; good magic, such as that used by Trobriand gardeners described by Bronislaw Malinowski, helps the natural forces along their regular paths. Traditional society tends to assume what anthropologist George Foster called "limited good": the necessities and luxuries of life are finite in quantity; if all people take just what they need, there is enough for all.

As it is harmful, sorcery works contrary to the natural order. It interferes with the natural movements of the forces and redirects them, and this is dangerous business; once dislodged, the forces of nature can run amok and injure the sorcerer or those near to him. It is assumed that the skilled sorcerer has methods that protect him from backfiring forces, but others do not. And, as sorcery is selfish, it upsets the natural distribution of goodness in the world; even though the sorcerer's aim may be personal enrichment, not direct harm to another, by accruing more than he needs, he automatically deprives others. These are further reasons why this form of sorcery is clandestine.

Sorcery has been described as using legitimate means—the principles of magic—for illegitimate ends. The best-known form of magical sorcery is the "voodoo doll," a southern U.S. form of image magic, which intends to harm a victim by harming an image of the victim. The image incorporates some features unique to the victim or some bodily effluvium or a piece of clothing that has been in close contact with the victim. For fear of sorcery, people are careful with their bodily leavings, especially those of vulnerable individuals: infants or the elderly or sick people. And sorcery has everywhere been used in feuding and warfare; in Africa today, inventories of offensive weapons seized from rebel combatants often include "charms."

The simplest and most widespread forms of magical sorcery are obscene gesture and curse. In the former, a person uses a part of the body as symbol to convey malevolent power, such as "giving the finger" in the West. Curse is the direct malevolent use of words whose meaning conveys some harm or misfortune. Curse must be distinguished from invocation;

for example, "God damn you!" is invocation, calling on the Almighty to condemn the other to eternal torment in hellfire. This is very risky, because the deity may be offended by such human presumption (taking its name "in vain"). "Go to Hell!" is a curse. It contains the same meaning but uses the power inherent in the spoken words, enhanced by the evil intent of the speaker and carried and energized by his breath, his life force.

Defense and Remedy

In traditional stable societies, where there is sorcery there will be defenses against it and remedies for misfortune caused by it. Sorcery "works" through the well-described placebo effect; the victim and his social network all believe in its efficacy, and he may indeed suffer the intended symptoms. In his famous 1942 description of "The Voodoo Death," Walter Cannon took data from various early reports, especially Australian Aborigines' beliefs in sorcerers' technique of "bone-pointing." He showed the deleterious physiological effects of the body's overproduction of adrenaline in response to prolonged intense fear and the rapid and dramatic relief that can result from the patient's being convinced by a healer that the evil has been removed.

It is universally believed that power can be drawn from one source and used magically by individuals. Religious texts and symbolic objects are frequently used as protective amulets on people's dwellings, workplaces, and bodies. Reproductive power is extremely strong, and representations of both male and female genitals are universal power symbols. Quick defense can be made by symbolic use of parts of the body, such as the Italian *mano fica*, the "fig hand," the clenched fist with the thumb protruding slightly between the first two fingers (a crude representation of the female genitals) or the *mano cornuta*, "horned hand," representing horns, which also are power symbols used around the world. Making the "sign of the cross" over one's chest and crossing the fingers are similar hasty protective devices.

Because sorcery is difficult to detect, divination is often involved, first in diagnosing it, then, rarely, in assigning blame. Bad spells can be nullified or deflected by stronger magical or spiritual power, and this is a frequent reason for the performance of magical rituals or supplication of spirits. Accusations of sorcery are not made lightly. Most often the sorcerer

is not identified; frequently, specific persons are suspected, but lack of clear evidence forestalls accusations. Conviction means penalty and social stigma, and false accusation rebounds upon the accuser. A trial by ordeal might be required, with both accuser and accused participating.

If a malady is caused by possession by a demon sent by a sorcerer, an exorcism must be performed upon the victim or his surroundings. This might be accomplished by the healer's invocation of a more powerful spirit, which is commanded to drive out the offending spirit, or by his own mastery and command of the possessing demon. Relief comes through the placebo effect.

Everywhere there are civil regulations against defamatory language. Literacy enhances respect for the power of the word; spoken words can be repelled, but the written word achieves an awesome, perhaps terrifying permanence. Protective and aggressive charms containing writing are common today, and modern laws against slander and libel attest to the continuing respect for the power of spoken and written words.

Explanations

Sorcery seems dysfunctional and disruptive to social order, and its universality presents a puzzle. Social analysts have seen various "social control" functions in sorcery beliefs; fear of being suspected of this terrible anti-social impulse tends to keep people mindful of their social manners. A "social-leveling" function of sorcery beliefs has been seen in egalitarian societies in the suspicions that accrue to stingy people and hoarders or people who inexplicably have more than they need, thereby depriving others.

It has been said that fears of sorcery support social hierarchies; people more powerful politically are often presumed to have access to strong supernatural power. There are clear political situations in which suspicions of sorcery are advantageous; the Duvaliers of Haiti strengthened their autocratic rule by actively encouraging the popular sense that they were powerful sorcerers, and many African leaders have forestalled their enemies by promoting beliefs that among their entourage were powerful sorcerers.

But at the most basic level, suspicion of sorcery is surely a function of the inevitable tensions that arise between individuals in social relationships, the same

sorts of tensions that generate witchcraft suspicions and conspiracy theories.

SPEECH, FOLK

The designation *folk speech* is one of various terms that have been used to describe the language of ordinary people as used for routine purposes on the everyday level of face-to-face oral communication. Such variation refers to the pragmatic rather than to the grammatical aspect of language, that is, to the way language is used to communicate within the context of social interaction as revealed in different patterns of discourse, rather than to the internal structure of the linguistic code as seen, for example, in dialect variation.

Folk speech can be differentiated from two other major intralinguistic varieties: dialect and style. Following M. A. K. Halliday, we can say that dialect is linguistic variety according to *users* (regional populations or social classes) while style is variety according to *use*. Since folk speech is a natural product of face-to-face oral communication, it can co-occur with whatever dialect variation is natural to the speakers, thus the two varieties, folk speech and dialect, can be treated separately. Style can be defined as the intentional selection of alternative forms within the linguistic code for some specific communicative purpose. For example, "He regrets that he is unable to attend" and "He's sorry he can't make it" are denotatively synonymous, yet everyone recognizes at once that the first is formal while the second is informal in its occurrence. Stylistic variations of this kind, which mark different levels of formality, are called registers.

Other registers within the stylistic repertoire of a language correspond to different domains of use such as journalism, bureaucratic communication, sermons, lectures, and so on, as well as to the selection of alternative forms for esthetic effect in literature. In so far as the restricted mode is an automatic response to speaking conditions and not a matter of conscious choice, it is not “variety according to use,” as is style. If, however, style is defined in its most neutral sense as simply “a way or mode of doing something,” folk speech can be described as an informal register within the variegated functions of a complex speech community, unless the speakers master no other stylistic variants.

As a separate variety, we can describe folk speech as the restricted as opposed to the elaborated mode of language use. Borrowing terms from literary criticism, we might characterize the restricted mode as thinly textured discourse, since fewer of the grammatical and lexical resources of the language are employed than in the thickly textured discourse of the elaborated mode, in which the full grammatical and lexical resources of the linguistic code are employed. The restricted mode is thus the language of implicit meaning while the elaborated mode is the language of explicit meaning. The thinly textured discourse of folk speech is characterized by the use of simple verb constructions and preference for the active over the passive voice. Syntactically, folk speech is paratactic, that is, it is made up of simple sentences with only a few conjunctions used repetitively and with little subordination of clauses. Indeed, there is evidence that in the languages of some nonliterate, pre-industrial homogeneous societies there is no subordination at all. Another feature of folk speech is the avoidance of impersonal pronouns as sentence subjects. Thus, “Everybody knows he lives here” is used instead of “It is known that he lives here,” and “A man used to come to town all the time” instead of “There was a man who used to come to town all the time.” Also, ellipsis and unfinished sentences are frequent in folk speech. The syntax of the more thickly textured discourse of the elaborated mode is hypotactic, that is, it consists of complex sentences employing a wide range of syntactic devices for conjunction and subordination. The use of impersonal pronouns as subjects is also frequent, as is the use of prepositions to mark both temporal and logical relations. More frequent use is also made of complex verb phrases as well as of the passive voice.

On the lexical level, the restricted mode involves the use of a smaller vocabulary with a high proportion of words of emotional content as well as the frequent use of expletives. Folk speech is also characterized by the rigid and limited use of adjectives and frequent use of formulaic expressions such as “I mean” and “you know”—what Bernstein called sympathetic circularity. The elaborated mode, however, draws on a larger vocabulary with finer semantic distinctions on higher levels of abstraction. Another feature of the vocabulary of folk speech is that lexical precision is focused on those activities closest to the activities of local endeavor while other objects and events remain unlexicalized. For example, plants that were not useful to German rural dialect speakers, or that were not aesthetically pleasing or were particularly harmful to them, were simply referred to as “weeds,” while attributes of those plants of particular interest were lexicalized in detail.

Even the more highly lexicalized domains of folk speech are poor in abstract terms but rich in concrete, particular ones based on local experience. A study of one local German dialect revealed that out of a list of 4,470 words only 210 were abstract, and out of 3,300 nouns collected in another region all but 420 were semantically concrete. For example, in one dialect the abstract word for “basket” was never used. In its place were seven different terms for different kinds of baskets employed for different purposes. It was also noted that the semantic range of abstract words tends to be more restricted in local dialects than in the standard language. For example, the word *Güte* with the broad semantic range of “kindness, goodness, excellence, purity, quality” is restricted in folk speech to only the quality of merchandise.

Another example of the preference for the concrete in folk speech is the use of concrete descriptive phrases instead of more abstract single words. Thus instead of “on account of his poverty” one hears “because he’s poor,” and instead of “after sundown,” “after the sun went down.” One also hears such locutions as “he’ll be home by hog-killing time” instead of “he’ll be home by winter,” and “when it gets green” or “when the swallows return” instead of “in the spring.” Often preference for the concrete takes on an ironic twist. Instead of saying that someone has been executed on the gallows, one might say that “he didn’t drown in the Rhine.” An Ozark woman too proud to accept welfare was reported to have said, “I’d sooner get me a tin bill and pick manure with the chickens.”

A touch of humor is also often added, as when in the Ozarks a young man was described as being so drunk “he had to hold on to the grass to keep from falling off.”

All speakers use the restricted mode of speech since it is a natural result of face-to-face oral communication. This is why many of the discourse features of the folk speech of local German dialects were the same as those found in colloquial speech. In both cases, a high degree of shared background information among interlocutors, together with the context of situation and cues such as intonation, body language, eye movement, and so on, make it easier for hearers to infer the communicative intention of speakers with recourse to fewer lexical and grammatical resources, thus the thinly textured discourse of this form of speech. When interlocutors share little background information, greater weight in communication is shifted to the inner structural resources of the linguistic code, thus the more thickly textured discourse of the elaborated mode. These pragmatic features have led John Gumperz to conclude that the difference between restricted and the elaborated speech is simply the difference between two modes of “signaling or calling on background knowledge.”

Folk speech has long been of interest to folklorists who are less concerned about its nature than the way it reflects the shared local cultural experience of folk groups. Such scholars include nonstandard dialects in their study of folk speech along with the stock of proverbial comparisons, proverbial phrases, aphorisms, adages, sayings, and proverbs that comprise the phraseological level of language. They also include in folk speech the study of names (onomastics) and argots (special use of language by different groups) as well as occupational vocabulary as it appears on the folk level. The ethnography of speaking provides the broadest perspective for the study of folk speech since that line of research examines the linguistic resources available within a speech community and their use in socially situated discourse to form meaning patterns of language use in both speaking practices and esthetic expression.

Folk speech has also been exploited by writers for stylistic effect to evoke the impression of local color and a sense of time, place, and situation as well as in the development of character. For those purposes, features of folk speech can be used in dialogue within a narrative written in the standard literary language, or it can be used for the narrative voice as is the case

of Mark Twain’s *Huckleberry Finn*. The fact that folk speech contains such rich stylistic possibilities is one reason why it stands out as a definably different variety in the linguistic variation of a speech community.

ANATOMY AND PHYSIOLOGY OF SPEECH

The computer revolution has added a new twist to the study of both anthropological linguistics and synthetic anthropology, as computer engineers and linguists attempt to design computers that can understand or reproduce speech naturally. Those involved in this endeavor are required to synthesize a large number of elements involved in linking computers and human speech across a spectrum of disciplines such as acoustics, artificial intelligence, digital signal processing (DSP), elocution, linear algebra, linguistics, physiology, probability theory, and psychology. Research into speech systems for computers began in the mid-1950s. While several speech system models are readily available for use on personal computers, they tend to lack the ability to follow the tonality and nuances of human speech. In principle, these models depend upon identifying segments of sound. The goal for newer models is that they will be able to produce more natural sounds by joining those segments as human voices do.

While it is unlikely that humans will be able to freely converse with computers in the near future, IBM, Nuance, and Speechworks have all begun experimenting with the use of computerized attendants that are expected to eventually replace the touch-tone phone menus that are so frustrating to the average caller. In 2001, some \$240 million

was spent on speech software, mostly by banks and airlines. By 2006, that number is expected to top \$1 billion. Many of the technological advances in designing computers that understand human speech have been derived from the work of deaf mathematician and computer expert Dimitri Kanevsky, who, in 1991, was the first to identify the method that allowed computers to respond to human speech without requiring a lengthy pause after each word. Using Kanevsky's algebraic algorithm, a number of voice-recognition products were subsequently marketed.

Kanevsky also developed software that allows special telephones to understand callers from around the world without the services of human transcribers. The use of voice translators has received a good deal of attention from those who are being called upon to interact with a multilingual world. Travelers who have been forced to resort to language dictionaries in the past have enthusiastically seized upon voice translators. Police officers, firefighters, and the military have also found that voice translators save lives and time when dealing with individuals who speak other languages.

In 2002, Kanevsky refined an earlier invention that allowed deaf individuals to interact with others without lip reading. He reduced a large laptop to the size of a tablet and gave it the ability to transcribe the sound of any human voice that it hears.

Visionaries believe that computers will eventually be able to communicate with humans without either speech or touch. In the spring of 2004, the National Aeronautics and Space Administration (NASA) announced that it was in the process of developing new technology that would allow computers using special software to connect with sensors placed on a user's chin and throat to receive words from brain signals.

— Elizabeth Purdy

SPENCER, HERBERT (1820–1903)

Herbert Spencer, a British social philosopher and sociologist, was a widely recognized visionary and the founder of the theory of sociocultural evolution, and

he had a major influence on Charles Darwin and his theory of biological evolution.

Born in Derby, England in 1820, Spencer trained as a civil engineer and then became interested in social and economic issues, joining *The Economist* as a subeditor (1848) and writing *Social Statics* (1851), a book in which he described the synergy of society based on a core principle of justice—the law of equal freedom—which became the foundation of classic liberalism and the quintessential theory of the state.

Social Statics served as the dawn of Spencer's theory of sociocultural evolution, which he developed as a hypothesis in "The Development Hypotheses" (1852), asserting that each species arose through adaptive changes of previously existing species. In "Progress: Its Law and Cause" (1857), Spencer further developed his theory of evolution, claiming that progress occurred along an evolutionary divergent timeline from homogeneous or undifferentiated to heterogeneous or differentiated. He applied this theory to the disciplines of biology, ethics, metaphysics, psychology and sociology, defining evolution as "a change from a state of relatively indefinite, incoherent, homogeneity to a state of relatively definite, coherent, heterogeneity."

Spencer's interest in organic evolution as well as general evolution led him to write that "life . . . has arisen by a progressive, unbroken evolution . . . through the immediate instrumentality of what we call natural causes." He applied his approach to a comparative scientific study of society based on evolutionary principles, an approach distinct from that of the French sociologist Auguste Comte. Spencer's approach required classification of all available ethnographic and historical data of human society and social behavior in order to derive generalizations.

Spencer visualized sociology as the focus of the study of the natural history of society, and he considered descriptive sociology to be the "only history that is of practical value" and comparative sociology to be a compilation of the lives of nations and the "subsequent determination of the ultimate laws to which social phenomena conform."

Spencer maintained that there were many parallels between biological organisms and human societies, and he often referred to society as an organic system of structures that are mutually dependent. To Spencer, social functions create social structures, and to this position he assigned the general law of organization that "difference of functions entails differentiation and division of the parts performing them."

Source: Courtesy, Wikipedia.

Spencer's *Principles of Sociology* stands as a significant contribution to the theory and understanding of evolution. His theory that humanity evolves from a relative, socially static, undifferentiated society to a utilitarian, socially dynamic, differentiated society where social structures and functions transform to meet needs is an organismic model of interrelated and interdependent structures and functions (from the inorganic to the superorganic) as social systems where consequences occur as "the survival of the fittest." His functionalist theory of evolution became known as Social Darwinism.

Spencer's social systems theory of evolution (statics and dynamics) gained popular appeal in the late 1800s, and it contributed to the intellectual revolution of the 19th century, influencing the development of anthropology, biology, political science, psychology, and most important, sociology. His theory was formulated on the construction of a paradigm of

ethnographic and historical data classified in a system of headings and subheadings. Spencer was the founder of systematic, inductive, comparative sociology which he called Descriptive and Comparative Sociology.

Spencer's contributions to anthropology and sociology are profound and beyond measure. He was among the first to claim that human society can be studied scientifically, and he ranks with Edward B. Tylor and Lewis Henry Morgan as one of the three prominent sociocultural evolutionists of the 19th century. His rejection of special creation and acceptance of organic evolution with increased integration stirred the public and inflamed the religious. Spencer's theory of sociocultural evolution together with Darwin's theory of evolution through "natural selection" revolutionized intellectual thought and social mentality. To Spencer, human social behavior is based on a normative order that conforms to natural or ultimate law, which defines the principles of human social organizational forms including marriage and the family, property, and equal freedom.

The influence of Spencer's works on modern social thought is omnipresent. Charles Horton Cooley, William Graham Sumner, William James, Émile Durkheim, Radcliffe-Brown, Thorstein Veblen, Simon Nelson Patten, and Edward L. Youmans were influenced by his works. His advocacy of individualism and laissez-faire based on the inheritance of acquired characteristics as imperatives of adaptation influenced 20th century capitalism, while his evolutionism brought strong reaction and rejection until the works of Leslie A. White, Julian H. Steward, and V. Gordon Childe helped anthropologists accept sociocultural evolution as a process of increasing structural differentiation and functional specialization.

SPENGLER, OSWALD (1880–1936)

Oswald Spengler was born in Blankenburg (Harz) in central Germany in 1880, the eldest of four children. As a young man, his family moved to the university city of Halle, where he studied Greek and Latin, mathematics, and the natural sciences. It was during this time, he also began to study the writings of Goethe and Nietzsche.

After graduation, he taught mathematics, physical sciences, history, and German literature. However, his heart was not truly in it, and upon receiving a large inheritance in 1911, he left the profession for good.

It was about this time that Spengler began to interpret contemporary events as parts of a more “global” trend. He saw the encirclement of Germany by the Entente powers, the increasing polarity of those nations, and a string of international crises as signs that Europe was headed off the cliff. His theory was only confirmed as the Great War of 1914–1918 saw unprecedented bloodshed and destruction throughout Europe. Spengler’s major work, *The Decline of the West*, has as its main point that historical civilizations (including our own) share a common life cycle and that there are readily identifiable patterns within each.

The book was an immediate success, first in Germany and then throughout Europe. Although professional historians dismissed the work as unscientific and amateurish, the man in the street found the themes easy to understand. Furthermore, as Germany struggled economically in the aftermath of the War, the decline of the West seemed to be at hand.

The Decline of the West has as its basic premise that world history is not linear but cyclical. Spengler used examples drawn from the ancient Egyptians, the Chinese, the Mayans in Mexico, the Greeks, and Western civilization. He saw human history as the perpetual record of the rise and fall of unrelated High Cultures and believed that he and his contemporaries were witnessing the twilight of European or Western civilization.

Spengler believed in the superiority of the “white” man. His 1931 book *Man and Technics* is an account of how throughout history the West has been unique in creating advanced technology. In it he warns of a future where the outer “colored” races eventually use that very technology against the West to destroy Western civilization. He was pleased with the National Socialist takeover in Germany in 1933 and

had even voted for Hitler in the 1932 election. This is not to say that he was in total agreement with Nazi racial doctrine. He criticized their failure to reach out to all Europeans in the coming battle (as he forecast it) against the foes of white men. He met Hitler in the summer of 1933, after which Spengler declared himself “unimpressed” with the Führer’s capabilities. In fact, his later work, *Die Jahre der Entscheidung*, chided the Nazis for “going it alone” against the world in the soon-to-come battle against the West’s enemies.

Spengler did not survive to see the Second World War that he had predicted. He died on May 8, 1936 of a heart attack in Munich. His views regarding the rise and fall of civilizations live on, however, as his major works have been both referenced and criticized by other historians and philosophers since 1922. Spengler’s ideas have forced us to take another look at all cultures, including our own, with an eye toward how we can perhaps prevent the failure of our own civilization.

SPIDER MONKEYS

Spider monkeys are members of the order Primates, formerly included in the family Cebidae but now placed in the family Atelidae. They belong to the genus *Ateles*, which includes four species. These New World monkeys are found throughout the tropical rain forest regions of southern Mexico and Central and South America. Spider monkeys range between 14–26 inches in length and have an average weight of about 15–22 pounds. They are slightly potbellied and have coarse hair that varies from beige to deep black. Spider monkeys exhibit sexual monomorphism; males and females are almost identical in size and color.

Spider monkeys have narrow hands with long, curved fingers that function as hooks to firmly grasp

tree branches, and most species lack an external thumb. They have extremely diverse locomotor abilities including arboreal quadrupedalism, suspensory behavior, and some bipedalism in the trees. A combination of long, lean appendages and exceptional agility assists them in making swift, acrobatic movements across the upper level of the canopy. Spider monkeys have a prehensile tail stretching from 24–36 inches that plays an important role in their arboreal lifestyle. The tail serves as a fifth limb as spider monkeys cross forest gaps up to 40 feet in length, sprawling out like spiders as they travel throughout the forest.

The social structure of spider monkeys is complex and generally referred to as fission-fusion. Spider monkeys form community units made up of approximately 15–25 members comprised of both sexes and a variety of ages. Females normally take on a more active leadership role than males, directing group activities such as traveling, foraging, and feeding. Although the spider monkey diet consists of an assortment of foods (leaves, nuts, seeds, flowers, insect larvae, and birds' eggs), ripe fruit is the main staple. However, because ripe fruits are an ephemeral resource in both space and time, spider monkeys split up into smaller foraging parties of two to eight individuals in order to reduce feeding competition among group members. The dominant females

usually have feeding routes that increase their foraging and feeding efficiency.

The spider monkey gestation period lasts close to eight months, at the end of which there is a single birth. Infant spider monkeys have a long period of dependence, and the strongest social bonds are formed between mothers and offspring. Not only do newly born spider monkeys remain black and nearly hairless for almost one year, but their mothers continue to carry and provide milk for them until they are around two years of age. Spider monkeys stay close to, and do not

attempt to travel independently of, their mothers until around age three. Females become sexually mature between the ages of four and five, while males do not reach full sexual maturity until after their fifth year of life. Unlike many other primates, grooming is not of great importance in spider monkey social interactions. This may be due to their lack of functional thumbs.

With half of the *Ateles* species being endangered, research continues in order to determine the reasons that they are at risk of extinction, as well as to assess what can be done to prevent further harm. In the Central American countries of Costa Rica, Nicaragua, and Panama, farming is a major contributing factor to the spider monkey's demise as vital habitat is lost to land cultivation. In addition, illegal hunting is also problematic. Spider monkeys have become an easy and attractive target, especially since they are relatively large and have a rather tame demeanor.

STEREOTYPES

Stereotypes are rigid clusters of overly simplified social and cultural characteristics conjoined into a single, imagined identity or schematic theory used to label a social group and assess members' character, attitudes, and behaviors. They offer comfortable, convenient filters to make sense of complexity and are inherent in the act of social categorization and perception. Based on beliefs, knowledge, and expectations, they often have moral and judgmental overtones, which are generally viewed as derogatory and offensive. Group stereotypes are never grounded in holistic descriptions of heterogeneous cultures or social groups but are centered on some initially observed cultural behavior or visual cue. This cue is then interpreted using the stereotyper's frame of reference and meaning structure, homogenized, and overgeneralized in an attempt at differentiation. Intergroup differences are minimized and intragroup differences exaggerated using confirmatory bias and routine simplification. Sometimes these judgmental snapshots stem from distortions or misunderstandings about a behavior or attribute seen in an initial cross-cultural or cross-group encounter. Rapid superficial assessments then combine with established assumptions—often based on gender, race, age, ethnicity, culture, or “strangeness.” Once established, a stereotype's condensing symbolism becomes tenacious and is used to justify subsequent actions toward the stereotyped group, a fact that has been apparent in colonizing situations, group conflicts, business dealings, or justifications of the status quo. People use stereotypes to rationalize asymmetrical power situations, validate prejudice, or in extreme cases to justify hostility, oppression, violence, war, genocide, or religious fanaticism.

While there has never been a comprehensive cross-cultural examination of stereotyping, it appears that stereotypic thinking is widespread and serves multiple purposes. The most important seems to be efficient information processing, memory formation, and categorization during enculturation, times of change, or when encountering a perceived threat. Stereotypes are used to simplify perceivers' thinking in new situations that require processing large amounts of information. They allow individuals and groups to rely on previously stored knowledge, conclusions, and assumptions, eliminating the need to

assess ambiguous or disquieting information that brings their assumptions into question. As such, stereotypes can be part of coping strategies because they keep groups distinct.

Stereotypes can emerge from a realistic visual image that is overgeneralized using a classic logical fallacy; for example, honored Lakota warriors did wear long feathered headdresses, therefore all Indians wear them. As a result, stereotypes are held to be “true” even when they have been recognized to be only partially correct. This process occurs because stereotypes reflect societal desires, fears, projections, and imaginative speculations, which are more important to people than “facts.” People want their assessments to be true because they uphold self-worth and cultural esteem; stereotypes recursively gain this pseudo-authenticity through repetitive, unquestioned use learned through standard processes of enculturation. Stereotypes also prescriptively define cultural expectations of acceptable behavior or proffer immutable “how not to behave” rules. This usage stems from the term's original (1725) denotation: a stereotype was the metal plate used in cylindrical printing presses. Just as there is the expectation that the metal “a” in the cylinder will print the letter “a” on the paper, so stereotyped social categories are fixed and conventionalized duplications. The category “mother” includes expectations of how mothers should act. If the stereotype is that all mothers are kind and gentle, when a person sees different behavior—such as yelling at a crying child—he or she jumps to the conclusion that that person is a “bad” mother. This assessment is done without obtaining any information about the circumstances. As ascriptions, stereotypes thus produce prototype effects.

Stereotypes work best if there is little contact with, and first-hand knowledge about, the people categorized. In this way, the categorizers do not have to deal with intracultural and intercultural diversity, which is messy. Americans today have little knowledge about American Indians, yet everyone theoretically can recognize an Indian. What they recognize, however, is the stereotype, based on phenotypes. This situation allows stereotypes to flourish and gain permanency because stereotypes are about the unknown but presumed known. And what is known is arbitrary and varies by culture.

Psychology has studied stereotypes to a greater extent than anthropology. While anthropology theorizes the cultural content of stereotypes in intragroup

relations, psychology is interested in the mental mechanisms by which stereotypes operate and influence interpersonal and intergroup perception and interaction as processes. A wealth of psychological theories have been developed to address the individual mechanisms that give rise to stereotypic thinking and the cognitive and motivational factors that contribute to their formation, maintenance, application, change and tenacity. Social identity theory sees stereotypes as a form of compensatory narcissism, while information theory views them as a way to encapsulate information compactly to ensure survival. Much research needs to be done to develop a unified theory of stereotypes and stereotyping that can explain why individuals and social groups stereotype and can assess its evolutionary implications and consequences, yet account for stereotyping as a cultural phenomena that varies by culture, time, and context.

STEWARD, JULIAN H. (1902–1972)

Julian Haynes Steward is best known for his seminal contributions to cultural ecology, multilineal evolutionism, archaeology, and ethnography of the Great Basin and Plateau region, ethnology of South America, the settlement pattern and salvage approaches in archaeology, irrigation agriculture and early civilization, hunter-gatherers, peasants, and area studies. Steward became the single most important individual in cultivating an ecological approach to culture and cultural change from the 1930s into the late 1960s. In his research, publications, and teaching, he persistently

developed a theoretical and methodological framework for studying cultural change as adaptation in which environmental influences were especially important.

Steward was born on January 31, 1902, in Washington, D.C. In 1918, at the age of 16, he entered the college preparatory school in Deep Springs Valley north of Death Valley, in eastern California close to the border with Nevada and at the western edge of the Great Basin. Local natural history was an integral part of school instruction and nature was part of his daily experience beyond the classroom.

After a freshman year at the University of California in Berkeley, Steward followed some of his fellow preparatory school students to Cornell University where he studied geology and zoology. His BA degree was awarded in 1925 at Cornell. Then Steward returned to Berkeley for graduate work in anthropology where he received a PhD in 1929.

In the late 1920s to 1936, Steward returned several times to various areas of the high desert environment that had been such a profound attraction to him at Deep Springs School. Now, however, he was devoted to field research in archaeology and ethnography, and this was the formative period in the development of his cultural ecology, aspects of which can be found in many of his early publications. He had avoided taking any side in the academic debate of his predecessors. Environmental determinists argued that the natural environment strongly influences human behavior, society, culture, and history. Environmental possibilists countered that the environment presents many opportunities allowing a wide latitude for human responses in which culture is decisive. Instead of arm-chair speculation and debate, Steward sought to subject the question of the relationship between culture and nature to direct empirical investigation through actual fieldwork on particular cultures in their habitat, although his own fieldwork mostly involved interviewing scattered elderly informants about their memory culture.

Steward believed that the environment had the greatest influence on societies with less developed technology. This reflects his Deep Springs experience, where relatively recent Euro-American ranching and farming contrasted with the ancient foraging life styles of the original indigenous occupants, two very different modes of adaptation. This contrast stimulated his interest in change through time, especially in relation to new technology and its social repercussions. The desert impressed on him the role of

water in human adaptation, a recurrent theme in much of his work, particularly with regards to demographic and economic factors in the evolution of early civilizations.

Through his ethnographic investigations on the Shoshone, Paiute, and other indigenous societies of the Great Basin and Plateau region, Steward specified three interrelated foci for field research on the cultural ecology of a particular society: the natural resources and the technology used to extract and process them from the environment; the behavior and social organization involved in the labor in these subsistence and economic activities; and the influence of these two sets of phenomena on other aspects of culture. The third component Steward termed the culture core, although he later retreated from that concept. Accordingly, by the 1950s Steward developed an ecological framework for describing, and to some degree explaining, a particular culture. His approach emphasized the relationships among the biophysical environment, natural resources, technology, labor, economy, and social organization. Steward discreetly rejected the dominant position of Franz Boas and his followers like Alfred Kroeber, namely, that culture and history were sufficient to explain all of culture. Cultural ecology was the focus of Steward's last fieldwork, a six-week trip to the Carrier people of British Columbia in the summer of 1940 where he worked mostly with one key informant.

In subsequent decades, Steward's cultural ecology was criticized on several grounds. His theoretical concepts, like the culture core, were not very clear and readily operational; his method was mostly intuitive; he was a functionalist with some of the pitfalls of that approach; correlations were confused as cause and effect relationships; and he ignored relevant aspects of biological ecology. In addition, Steward focused rather narrowly on subsistence economy to the neglect of many other important factors, such as population dynamics, natural hazards, political institutions, religion, and the larger regional and world systems. His biographer, Kerns, has also revealed male gender bias in his work, especially his concept of the patrilineal hunter-gatherer band which in turn contributed to the "Man the Hunter" image. In addition, Steward's ethnographic field methods involved interviewing individual elderly informants in English or through an interpreter to record memory culture, a common practice at the time. Like most anthropologists until recently, Steward focused on traditional culture and

ignored the colonial situation that oppressed indigenous societies, assuming the inevitability of their socio-cultural assimilation or even extinction. Nevertheless, Steward, far more than any other single individual, launched ecological research in cultural anthropology and archaeology in America. His successors, including his critics, built and continue to build their own work on the basic foundation he established.

Steward's methodological approach, which he called multilinear evolution, was to select for detailed comparison a small number of particular cultures that were in similar environments (e.g., same types of desert or forest) and at the same level of sociocultural complexity (family, tribe, or state). The cultures selected should be widely separated geographically to avoid the possibility of cultural similarities arising from diffusion. Consequently, similarities in the sample of cultures that Steward selected would be the result of parallel adaptations in the sense of similar responses to similar environmental conditions.

This thinking fed into the evolutionary typology of political organization still used to this day by many anthropologists of band, tribe, chiefdom, and state. However, Steward rejected 19th-century unilinear evolutionism, the idea that all societies inevitably pass through a series of stages from simple to complex cultures. Instead, he envisioned far more complex phenomena with multiple lines and rates of cultural evolution, each depending on the variables in specific situations. Actually Steward had a deep revulsion to any grand theorizing or dogma. Unlike another neoevolutionist, Leslie White, who was concerned with universal laws of culture, Steward searched for specific cause-effect relationships in a limited set of circumstances and phenomena.

Steward's multilinear evolutionism was variously criticized for demonstrating correlations rather than causality; using inadequate sampling and avoiding statistics; confusing method (multievolutionism) and process (multilinear evolution); and neglecting negative cases where postulated relationships between culture and environment might not be sustained. Nevertheless, several cases of parallel adaptations in cultural evolution in different regions of the world identified by Steward remain widely accepted to this day by many archaeologists and cultural anthropologists.

From 1935 to 1946 Steward worked at the Smithsonian Institution in the Bureau of American Ethnology. At the Smithsonian, one of Steward's

achievements was to conceive and edit the monumental *Handbook of South American Indians* in seven volumes. However, Steward had a great deal of assistance from Robert Lowie, Gordon Willey, and especially from Alfred Metraux, the latter a specialist on the ethnology of that continent. This benchmark publication included contributions from more than 100 authors from a dozen countries, was organized on the basis of cultural types, and identified major theoretical issues that subsequently guided research for decades. Later, Steward, together with Louis Faron, published a synthesis of this handbook that became a standard textbook on the anthropology of the continent.

While at the Smithsonian, Steward also developed the Institute for Social Anthropology and served as its first director. It was focused primarily on the changing economy of peasant communities in Latin America and yielded more than a dozen monographs by various research associates, many of them Steward's students. After World War II, Steward contributed to the establishment of area studies, including an innovative project on Puerto Rico and subsequent studies elsewhere in Latin America and in Africa and Asia.

The Puerto Rico project was one of the first efforts by anthropologists to analyze a national society. Steward described Puerto Rico as an American colony. This and other research initiated by Steward also contributed to the development of modernization studies, dependency theory, and world systems theory, especially through some of his students and associates like Sydney Mintz and Eric Wolf. Simultaneously, such work eventually contributed to the foundation of political ecology, which has flourished since the 1990s.

Steward's cultural ecology certainly continues to strongly influence anthropological research on the relationship between culture and nature. In contrast, his multilinear evolution has not received as much attention, and he lost interest in it as well in later years. Steward's influence is seldom adequately acknowledged by subsequent researchers who are studying what essentially amounts to cultural ecology or multilinear evolution. Nevertheless, in 1952 Steward was awarded the Viking Fund Medal in General Anthropology, and in 1954 he was elected to the National Academy of Sciences, the latter quite rare for any social scientist during that era. Also, several of his former students recognized him in a collection of essays edited by Manners in 1964. Then in 1969, graduate students at the University of Illinois honored him by establishing the *Journal of the Steward*

Anthropological Society. Steward died on February 6, 1972. An obituary by Manners in 1973 includes an appendix listing Steward's more than 200 publications. From the 1930s into the 1960s, Steward was one of the main pioneers in the development of a scientific, empirical, materialist, behavioral, ecological, and evolutionary approach to explaining culture and cultural diversity. Steward himself was as extraordinary as his contribution to American anthropology.

Stonehenge is one of the most recognized formations of megalithic architecture and has a long history of speculation as to its builders, age, function, and changes over time. Located on the Salisbury Plain in Wiltshire, England, it is one of over nine hundred such circles of standing stones in Great Britain alone. Thousands more are evident in France (especially along the coast of Brittany), Spain, Denmark, Italy, and Malta.

Megalithic (mega = large, lithos = stone) architecture is generally characterized by three components: a tumulus; a large artificial mound or communal burial site; and a collection of large stones. It is one of the major characteristics of the western European Neolithic age and represents one of the earliest known stone architectures in the world. This architecture appeared from the fifth millennium B.C.E. as the agrarian way of life compelled a more sedentary existence. It can be termed simple when it involves a single standing stone, a menhir, placed in stark contrast with the surroundings; open but more complex

if many standing stones are arranged in a circle, semi-circle, or aligned in parallel rows; and closed when the stones are used to construct a burial chamber and covered with a tumulus.

A henge is an English term denoting a usually circular, prehistoric structure and earthworks, which can consist of a ditch, mound, wood, and a series of standing stones, of which Stonehenge provides one of the most striking examples.

The construction of Stonehenge has been divided into roughly three periods. The first division, using radiocarbon dating methods, is calculated at ca. 3000 BC and was composed of a circular enclosure surrounded by two banks of earthworks, with the outer bank 380 feet in diameter, 8 feet wide, and about 3 feet high, and with a ditch between. The ditch varied in width between 10 to 20 feet and 5 to 7 feet in depth. Artifacts taken from the ditch confirm the date of construction. The inner bank was composed of a local chalk work about 6 feet high and 20 feet wide, with a diameter of 320 feet upon which were positioned a pair of portal stones. To the northeast was a 35-foot entrance or avenue with a standing stone set back a short distance. This naturally shaped standing or heel stone, weighing about 30 tons, is about 20 feet long by 8 feet wide by 7 feet thick, with the lower 4 feet buried in the ground. It is inclined inward toward the circle at an angle of 30° from the perpendicular but is thought to have been erect originally. The stone is composed of sarsen, a very hard sandstone with a source at Marlborough Downs some 20 miles to the north. Stonehenge is composed of a variety of local materials and denotes a familiarity with the geological composition, texture, durability, and color.

Toward the end of this period, 56 Aubrey or X holes were dug inside the circle and varied from 2.5 to 6 feet in width and 2 to 4 feet in depth, spaced rather evenly in a 288-foot diameter circle. These holes were named after their 17th-century discoverer, John Aubrey, who described the filled-in circles that bordered the embankment. He speculated that

Source: © iStockphoto/René Mansi.

Stonehenge served as a temple and that the avenue was oriented toward the point on the horizon where the sun would rise on the summer solstice. The heel stone added further weight to the directional hypothesis as it is placed in a direct line of sight for an observer standing exactly in the middle of the circle.

Four points within the circle denoting four post holes form a remarkably accurate rectangle, which may have helped in setting out the site or, according to American astrophysicist Gerald Hawkins, may have established a position for observation of the sun and moon. But one of the certain functions of the first Stonehenge was an interment site for at least 55 cremation burials found at various locations, some dated soon after the original site was completed.

Stonehenge may have retained this shape and its structure for centuries, but eventually the site was altered. During a second phase, the main new work done was a planned but partially completed double circle of blocks of bluestone. For the most part, they are made of dolerite, blue sandstone, and limestone. The chief deposit for the dolerite is the Prescelly Mountains in Wales, some 150 miles away, although bluestone blocks were present in a neighboring area centuries before Stonehenge was built. The avenue was reconstructed and followed a winding route from a repositioned entrance down to the Avon river some two miles away.

Before the circles were finished, major social and political upheavals took place and the stones were dismantled and the double ring holes filled in. Alterations were begun during this third period of

Source: © iStockphoto/René Mansi.

reconstruction. More than eighty massive sarsen blocks, some up to 50 tons, were brought in from Marlborough Downs near Avebury, 25 miles away, and Stonehenge began to take its present form.

How these stones were conveyed, the amount of human energy expended, the time span, and the engineering expertise required are all daunting achievements. On a circle with a diameter of 100 feet, three upright sarsen stones were positioned and capped with a continuous ring of lintels in the center of the site. Within this circle, five even more enormous trilithons, or formations, consisting of two uprights supporting a lintel, were positioned in a horseshoe formation. These are the stones that dominate the landscape today and are the prominent feature at Stonehenge.

When these stones were in position, the discarded bluestones from the second period were dressed and erected in an oval setting inside the sarsen horseshoe. Its precise form is uncertain as they were dismantled once again and rearranged in their present form in a circle between the sarsen circle and the horseshoe.

A final discovery in 1923, Y and Z filled-in holes, formed two concentric rings of pits dug about 20 feet apart around the outside of the circle of stones. These may have been intended for a new placement or replacement of stones that was never carried out.

The major impact of Stonehenge is two-fold. As an engineering feat, it speaks of a society possessing the manpower, social organization, and engineering skills

necessary to complete such a task. As to its astronomical significance, there are some striking circumstances of location and structures. The particular latitude of Stonehenge allows for the direction of sunrise at the summer solstice and mid-summer rising full moon at its extreme southerly standstill position to be at right angles through use of the rectangle formed by the four stations. Had its position been a few miles north or south, there would have been misalignment. The position also gives a clear view of the horizon for 360° for celestial

sightings. The different heights of certain stones, such as the Heel Stone and Station Stone, enabled an observer at the center to use the tops of these stones to line up with the distant horizon, thereby facilitating observations and alignments.

Stratigraphy is the science of rock layering, with particular concern for composition, geographic distribution, and geological and chronological importance. This discipline also involves the interpretation of rock strata in terms of mode of origin and geologic history. As a main branch of sedimentology, stratigraphy generally relates the large-scale vertical and lateral similarities between units of rock layering to environment of deposition. Those relationships are defined

by lithologic and physical properties, geographic position, distribution, paleontological characteristics, and age relationships. Stratigraphers, using these properties and details of a sediment's composition, structure, and texture can then synthesize aspects of environmental geology and, moreover, interpret the broader aspects of Earth's geologic history.

Any stratigraphic investigation only becomes productive with a proper understanding of sedimentology, as stratigraphy is more a progeny than sibling of sedimentology. Formally, sedimentology is the study of natural sediments, both lithified (sedimentary rocks) and unlithified, and of the processes by which they form. Sedimentology includes all processes that give rise to sediment or modify it after deposition. These processes may include weathering, which breaks up or dissolves preexisting rocks; transportation; deposition; and diagenesis, which chemically and physically modifies sediment after deposition and burial, converting it into sedimentary rock. Sediments such as mud, sand, and gravel deposited by mechanical processes are known as clastic sediments, whereas those deposited predominantly by chemical or biological processes (limestones, dolomites, rock salt, chert) are known as chemical sediments.

Sedimentologists classify sedimentary rocks according to origin and size of included particles. However, the vast array of conditions by which sediments accumulate has borne a great number of sedimentary classification schemes giving rise to hundreds of sedimentary types, which invariably overlap. To complicate this system, most sedimentary rocks are, at least in part, made of several types of sedimentary rocks.

In order to make greater sense of the complexities of sedimentary relationships, classifications and hierarchical organizations were produced to give clarity and uniformity to stratigraphic analysis. Lithostratigraphic units in descending order are the supergroup, group, formation, member, and bed or stratum. The formation is the fundamental unit of stratigraphic geology, just as the cell is fundamental to biology. A formation must be lithologically distinct and large enough in scale as to be mappable. These classifications are defined strictly on the basis of lithology. Boundaries between units, including formations, are placed at the position of distinctive rock change or a distinctive erosional surface. In this manner, the divisions between units have the least possible ambiguity.

All rocks, whether metamorphic, igneous, or sedimentary, weather at the surface of the Earth.

Metamorphic and igneous rocks are formed at temperatures and pressures that are not seen at the surface so when these rocks are brought to the surface they become unstable. In the absence of air, most minerals in these rocks would remain intact for millions of years; however, because of Earth's climate, water, and atmosphere, these minerals break down and convert in a predictable sequence. The new minerals that will eventually form sedimentary rocks are stable at lower temperatures and pressures and are very slow to convert.

Sometimes difficult to distinguish from sedimentology, stratigraphy is specifically concerned with the layering and orientation of sediments. This outgrowth of sedimentology is based predominantly on the law of superposition, which presumes that in a normal sequence of rock layers not heavily disturbed or overturned since their deposition, the youngest rocks will lie above older rocks. Stratigraphy is primarily concerned with stratigraphic nomenclature, lithostratigraphy, chronostratigraphic and biostratigraphic series, and correlating specific successions between regions. From studying stratigraphic sequence of depositional layers, the geological history of a region or outcrop can be reconstructed. Stratigraphers must account for such factors as the average rate of deposition of the various sediments, their composition, the extent of the strata and any incorporated fossils to construct a proper analysis. These sequences are then correlated to those of similar age in other regions with the ultimate aim of establishing a consistent geochronologic sequence for the entire Earth. In areas where the strata have undergone folding, faulting, and erosion, stratigraphic techniques are used to determine their correct sequence.

In order to properly reconstruct a stratigraphic sequence of rock layers, uniformity among the scientists performing fieldwork must exist so that each sequence can be arranged in approximately the same manner. To this end, and to ensure uniform usage of stratigraphic nomenclature and classification within the field, a stratigraphic code compiling the principals and practices of stratigraphy was developed. The latest version of this code, known as the North American Stratigraphic Code, was published in May, 1983 by the North American Commission on Stratigraphic Nomenclature and is widely accepted by North American geologists.

Great efforts are made in stratigraphy to reconstruct and interpret ancient environmental conditions through stratigraphic correlation. Stratigraphers use

correlation for most practical applications; there is indeed a great monetary benefit from understanding where fossil fuels and other raw materials can be located based on the lithology of sediments. Thus, correlation of sediments becomes vital to any future geologic endeavors as globalization necessitates greater material allocation. The location of fossil fuel reservoirs is intimately tied to the ancient environments in which they were originally deposited. For this reason, reconstruction of ancient environments and paleoclimates has become a foremost concern for many geologists. Most readily available hydrocarbons used in the modern age are extracted from sedimentary rocks, as fossil fuels are, on occasion, the last stop in the decomposition of rocks yielding their primary constituents. Sedimentary rocks are also responsible for aquifers and are host to a wide variety of metallic and nonmetallic ores.

Seismic phenomena on the earth have given sedimentologists and stratigraphers the opportunity to see below the surface and unlock architectural mysteries of subterranean bedding. However, scientists need not wait until an earthquake strikes near their research area to extract information about the subsurface. Artificially generated seismic waves are used to obtain information regarding geologic structure, stratigraphic characteristics, and distributions of different rock types. Seismic stratigraphy was created to study the seismic data for these purposes.

Sequence stratigraphy is another branch of stratigraphy in which the cycles of worldwide ocean level changes are studied in rocks, preserving these marine transgressions and regressions that are then correlated to other time-equivalent rocks around the world. The principal of sequence stratigraphy is intimately linked to the assumption of cosmopolitan eustatic sea level changes. A sequence is representative of a complete cycle of the rise and fall of base sea level. Sequence stratigraphy is truly a method of interpreting stratigraphic data initially deduced through seismic data, then made applicable to an outcrop or well log data. Well logs are produced from data obtained from measurements of electrical conductivity, transmissibility of sound waves, and emission of nuclear radiation in the rocks adjacent to the well bore. The variations in measurements reflect the gross lithology of the rocks surrounding the bore hole. An instrument known as a sonde that is designed to measure velocity of sound waves, electrical resistivity, and natural or induced gamma radiation emitted by the

rock then relays its measurements back to the surface and is recorded onto digital tape. As the sea level swings from highstand to lowstand, a progression of depositional tracts are laid down, being preserved in the rock and recorded in well logs. Typically, sequence stratigraphy focuses on clastic sediments deposited on continental margins because these sedimentary environments are particularly affected by cycles in relative sea level change. The sequence concept was a revolution for stratigraphy and although not all geologists agree that reliable global sea level charts can be assembled from sequence stratigraphic data, most agree that these changes do affect the sediment geometry and rock unit distribution on continental margins or within time-equivalent sedimentary basins.

A relatively new branch of stratigraphy, known as magnetostratigraphy, applies concepts of geomagnetism to old rocks, allowing stratigraphers to reconstruct a detailed magnetic polarity time scale for the Earth. The primary application of magnetostratigraphy is as a tool to correlate marine strata. This discipline becomes appreciated when paleontologic or lithologic correlation is difficult using traditional methods. Mostly, the phenomenon of polar reversal acts as a contemporaneous, synchronous event that provides a precise tool for chronostratigraphic correlation. However, magnetostratigraphy is not limited to marine sediments and its techniques have been expanded in recent times to correlation of on-land sections. Therefore, most work in magnetostratigraphy in the future will correlate older on-land strata, thereby extending the data for polarity shifts further back in geologic time. Combining magnetostratigraphy, sequence stratigraphy, and paleoclimatic data, anthropologists can determine the duration in which a fossil or artifact locality was used. The paleomagnetic data from the Peking man site of Zhoukoudian suggests that the deposits of human fossils and artifacts endured from approximately 500 to 230 thousand years ago.

The incorporation and catalog of fossil remains has played a key role in most analyses of sedimentary rock younger than the Cambrian explosion of life. Fossils have been a most important means of correlation because, as a result of evolution, rock strata of approximately equal age exhibit similar flora and fauna. Dating and correlation of stratified rocks by means of fossils is known as biostratigraphy. The benefit to rock strata and fossils is mutual; fossils localized in strata can be dated using relative and absolute

dating, and in so doing provide a date to the sediment itself. The fundamental unit in biostratigraphy is the biozone. This biostratigraphic unit is a body of rock characterized by its fossil content, making it distinct from adjacent strata. The simplest form of biozone is the taxon range zone where the zone is defined between the first (lowest) and last (highest) occurrence of a single genus, species, or higher taxon. However, biozones can incorporate multiple taxonomic groups to define a range. In anthropology, most fossil specimens found around the world owe much of their importance to the date prescribed to them from stratigraphic paleontology or biostratigraphy.

All rocks, whether igneous, metamorphic, or sedimentary hold some clues to their origin and the environment. However, sedimentary rocks, with their structures, textures, fossils, and compositions provide a matchless insight into past environments, climates, ecosystems, orientation of ancient continents, and mountain systems that have long since vanished. The task of deciphering, compiling, understanding, and utilizing the evidence locked in strata is the stratigrapher's primary charge.

STRATIGRAPHY

During the second half of the 19th century, the International Geological Congress (IGC) was founded and tried to homogenize the standards for a common stratigraphic scale. Yet, its attempts failed and it was not until the 1960s that the International Union of Geological Sciences (IUGS) formed a Commission on Stratigraphy to work again on that topic. Modern stratigraphic systems bring

together two scales that are interpreted with the help of other dating methodologies. A time scale (defined in terms of eons, eras, periods, epochs, ages, and chrons), for which each division is defined by its beginning and ending points, is used in conjunction with a scale of rock sequences (described through systems, series, stages, and chronozones). These schemes are then combined with other dating techniques—such as radiometric dating, paleoclimatic dating, and paleomagnetic determinations—which were developed during the 20th century. This combination of different methodologies has resulted in a less confusing terminology and in increasingly more consistent information on which to draw conclusions about Earth history.

— Luca Prono

STRUCTURALISM

Structuralism emerged in the 1970s as a departure from the theoretical foundations of structural functionalism. It is among a variety of approaches to the study of social structure based on the general premise that there exist underlying structures that form the foundation for a social reality that only appears to be variable and changing. From the constructionist perspective, social structure is viewed as being either intentionally or unintentionally created by social agents. It is also used as a methodological or analytic tool by some social scientists to explain the regularity of social action by placing unpredictable behaviors outside the model. For structuralists, structure is recognized as the underlying force that drives social action, which in itself is viewed as merely a manifestation of a primary but hidden reality that lies beneath the level of consciousness. From this view, structures do not change, only the externalization of these structures in terms of changes in human action. The goal, therefore, of such analysis is to reveal the hidden universal and relatively constant social laws that influence the systems of society at the interaction, group, and institutional levels. This perspective deemphasizes the influence of individual agency, or individuals acting and choosing voluntarily.

Darwin, Spencer, Durkheim, Marx, and Freud took a structural approach to define their worldview, and planted the seeds for what was to become structuralism. Each of these individuals saw, from his unique perspective, a system of structures that was both greater than the sum of its parts and the cause of behavior rather than its result. Building on these perspectives but taking a linguistic turn, Ferdinand de Saussure (1857–1913), a Swiss linguist who is generally considered the father of structuralism, concluded that all social facts and patterns could ultimately be seen as resulting from the structures of language. Like Freud and Marx, Saussure concluded that it is structures that determine social interaction, not individual agency. Once a language is developed, the words and the thoughts they trigger become one entity, which then forms the social patterns incorporated as part of a particular culture. Language becomes autonomous and self-sustaining, allowing the subject to be undermined or totally ignored.

Formalizing these concepts into a single school of thought, Roman Jakobson wrote in 1929, “Were we to comprise the leading idea of present-day science in its most various manifestations, we could hardly find a more appropriate designation than *structuralism*. Any set of phenomena examined by contemporary science is treated not as a mechanical agglomeration but as a structural whole, and the basic task is to reveal the inner . . . laws of this system.” Lévi-Strauss, a French structural anthropologist who knew Jakobson and was influenced by his work, as well as by the American school of anthropology, studied these inner laws not by looking at the observable details of a society, but instead by examining what he felt to be universal structures of the mind that manifested themselves in signs and myths. Where Saussure felt that the primary structures of society were rooted in language itself, Lévi-Strauss looked into a culture’s myths, its literary traditions, and its guiding principles.

All forms of structuralism tend to see structure as the defining factor in determining social activity, often at the expense of human agency. It examines how a culture creates meaning for itself through its patterns of structured activities. There exists a sharp division between structuralists who believe the term refers to observable patterns of social practices, such as roles, norms, and language and those who see structures as the underlying principles upon which social patterns are built. This divergence of perspectives has never been successfully resolved, but opened the door for the

school of post-structuralism, which is particularly critical of structuralism’s inability to deal with the “temporality” of reality and the subsequent social changes that occur over a culture’s history.

Post-structuralism combines the structural linguistic approach of focusing on language, or more specifically on text, with the idea that social reality is merely the superficial manifestation of underlying linguistic structures. The primacy given to the unconscious by Freud and Lévi-Strauss was used by post-structuralists to disavow the legitimacy of all texts, since a text is nothing more than an expression of the writer’s unconscious. Therefore, texts cannot be understood by examining their content, the story, but rather must be deconstructed into linguistic formations or codes that are representative of all cultural texts.

It concludes that ultimately there is nothing real except words and how they are used together to form texts that literally construct reality. And, because it is people that invent and use words, they do in fact have significant agency in creating their reality and are not wholly proscribed by underlying or external forces. This perspective then allows for language to be used to change reality over time.

Two major proponents of this school are the French authors Derrida and Foucault. Their work, often criticized for being opaque, had an important impact on sociological thought. Both felt that the use of language by individuals does not create subjective meaning, but that the creation of language is “anonymous” and therefore without agent or subject. Throughout his varied and controversial works, Foucault attempts to demonstrate how systems of categorization structure our beliefs and practices, as well as what we think of as our knowledge. However, for Foucault, this knowledge is really the pretext for authorization and power. In other words, the stories or texts created by individuals are really the method by which society authorizes those in power to control those who are not.

Taking this critique of structuralism one step further, Derrida tries to demonstrate that the ability to describe and understand structures requires the writer, or scientist, to be somehow outside, to transcend, the structures being described, which he says is impossible. He concludes that individuals can never successfully stand outside their cultures and objectively study the structures within their culture, and therefore, there is no legitimate scientific methodology for interpreting

cultural structures. Conversely, the investigator who attempts to understand the structures of another culture can do no better than to superficially describe those structures because interpreting another culture's structures always involves the subjective perceptions of the observer and is necessarily suspect. Acknowledging this arbitrariness, Derrida focuses his investigations more on the act of writing than on oral or spoken communication. He takes this perspective, at least in part, because writing fixes the communication in time and exploits the arbitrary nature of both the act of signifying and of meaning itself.

In the end, these diverse structuralist and post-structuralist approaches to the understanding of social and cultural phenomena and to the cultural methods used to create meaning, have, according to recent criticism by Giddens and others, led down a path to their own demise. According to Giddens, the structuralist tradition has been unable to handle the very issues it raises. Structuralist theory takes its own conflicting ideas and codifies them in terms of binary oppositions, but never truly resolves these opposing forces. For Giddens, the structuralist attempt to deny the agency of the individual and the importance of subject has been misguided. "Social agents, not social theorists, produce, sustain, and alter whatever degree of "systemness" exists in society." Giddens goes on, within the general theory of structuration, to suggest that there can be reconciliation between structure and action because there is a "duality of structure." He contends that we can move beyond the contributions and limitations of structuralism by looking at both how structural properties are generated and sustained as well as what circumstances agents need to reproduce or change those structures.

CLAUDE LÉVI-STRAUSS

Claude Lévi-Strauss has been called one of the 20th century's greatest intellectuals. He is a French anthropologist whose work in ethnology led to the development of structuralism as a method for understanding society and culture. Lévi-Strauss was born into a Jewish intellectual family in Brussels, Belgium, in 1908. His father was an artist.

Lévi-Strauss studied law and philosophy at the Sorbonne University in Paris. He then taught in a secondary school. In 1935, he joined a French cultural mission to Brazil as a visiting professor at the University of San Paulo. From 1935 to 1939, he taught at the University of San Paulo. During these years, he made several expeditions into the Amazon rain forest to do ethnographic fieldwork.

Source: © Veldman Annemiek/CORBIS KIPA.

In 1939, Lévi-Strauss returned to France to aid the World War II effort, but he fled to New York after France was invaded by Germany. For the remainder of the war, he taught at the New School for Social Research, where he formed professional relations with Franz Boas and Roman Jakobson.

Lévi-Strauss returned to Paris in 1948. He was awarded a doctorate by the Sorbonne after he submitted as his major and minor theses *The Family and Social Life of the Nambikwara Indians* and *The Elementary Structures of Kinship*. The latter work was published in 1949 and was immediately hailed as an important contribution to the anthropology of kinship.

In 1959, he accepted the chair of social anthropology at the College de France. Around this

time, he published *Structural Anthropology*, a collection of essays about structuralism. He also worked to develop anthropology as a discipline in France by creating places of study, including the Laboratory for Social Anthropology. This was also the home of the journal *L'Homme*, which would publish anthropological research. Lévi-Strauss was elected to the Académie Française in 1973. He received the Meister-Eckhart-Prize for Philosophy in 2003.

Lévi-Strauss used structural analysis to study mythology. He sought to answer the question of why myths from around the world are so similar. He found the answer not in their content but rather in their structure. His legacy includes his theory on how the human mind works, which may be his most important scientific contribution. He argued that people progress from a natural state to a cultural state because there are laws or mechanisms in their brains. This means that humans really do not possess free will but instead are the products of mechanical evolutionary forces.

— Andrew J. Waskey

STRUM, SHIRLEY C.

Shirley Strum has had an interest in primitive life since she was a child. This interest was furthered in a number of ways. She successfully pursued it at Stanford University where she earned a PhD in anthropology. This brought her to Kenya where she found a group of baboons nicknamed the Pumphouse Gang. She has studied primates for at least 29 years and has focused on a number of different areas of primate behavior.

Professor Strum teaches a course in “Conservation and the Human Predicament” at the University of California at San Diego during the spring semester. Her specialty is physical anthropology, reflecting her professional training and field experiences. However, most of her time is spent in Kenya where she continues to study baboons. She is also the director of the Uaso Ngiri Baboon Project. In addition, she has developed an appreciation for conservation and has worked to support it. Professor Strum’s work will be of interest to scholars concerned with evolutionary

theory regarding human beings. What she has found may help explain and account for some of the characteristics of present-day humans.

SUBCULTURES

The concept of subculture has a particularly strong, yet controversial trajectory in the social sciences in general and anthropology in particular. The concept was formulated in early social theory to address a variety of sociocultural forms that are included in a totality, be it society or national culture. These forms could be the subdivisions of national culture, minority groups, immigrant or refugee populations, or rural/semi-rural communities, for example. Subcultures were seen by many authors as both “cohesive social systems” and variants of a national culture, cultures within a cultural world. For instance, various community studies of rural populations were conceptualized as completely integrated systems, subcultures that are autonomous from the works of the nation-state. This perspective was mostly shaped by the modernist paradigm, which views society as an integrated whole, a thing which can be understood through concepts of order, systems, shared norms, and values.

The urban ecological model calls for ethnographic methods to study peculiar urban situations (e.g., ghettos, social and economically isolated neighborhoods) that generate particular conditions for emerging norms and behaviors that contrast with those of the dominant society, and was put forward by the School of Chicago. In the United States, the Great Depression and the aftermath of World War II led to mass migrations of diverse populations and

structural transformations in major cities, which contributed to increased marginalization of minorities, violence, illegal drug trafficking, and crime. These created conditions that fostered youth frustrations and fed their articulations into subcultures, such as gangs, with complex norms, structures, and behaviors that are contrary to the mainstream society. The ethnographic study of subcultures brought to light in sociological and anthropological discourses complex sociocultural processes that underlay these behaviors. Indeed, the social sciences were called upon to help formulate public policies that target the minorities and the marginalized. “Subculture” in these studies was a keyword that was widely understood as a metaphor for social pathology (for many authors, the analytical framework was formulated in terms of “deviancy” or “anomy”). It referred to a process through which marginalized groups took their marginalization as a condition for transgression, yet not for protestation or resistance.

The neo-Marxist assumptions that underwrote the cultural studies (formulated through the British scholars at the Birmingham Centre Contemporary) favored a conceptualization of subculture as resistance. Drawing from Antonio Gramsci’s concept of hegemony and Louis Althusser’s ideology, its tenets suggested an approach to subculture that emphasizes both the specificity of (sub)cultural practices and the historical process that sustains these practices in the first place, as well as the dialectic of social conditions and consciousness. Although “subculture” became the theme of predilection for cultural studies, anthropology’s unique contribution was in understanding the meanings of these practices as related to some form of resistance.

Although subcultures as phenomena remain understood as dominated cultures (reactive to or expression of resistance against the dominant culture) and as such associated with the working class, (sub)cultural practices are co-opted and commodified by larger socioeconomic processes. This is the case in terms of youth cultural practices, for example rap music in the United States, where, with the incorporation of youth culture into popular culture, the concept of subculture becomes difficult to delineate. The role of anthropology is thus critical in defining the future of this concept in a globalized world.

SUDANESE SOCIETY

Sudan is an ancient African nation; early Stone Age or Paleolithic sites suggest dates as early as 250,000 BCE. The states of Nobatia, Mukuria, and Alwa adopted Christianity for centuries until they converted to Islam in 1315. Today, Sudanese society is multi-ethnic and multi-religious.

The medieval Funj Muslim kingdoms of the Blue Nile might well be descendants of the Shulluk of southern Sudan; the Ingessana and Nuba of central Sudan might well have been the same northern Nubians who had ruled both Egypt and Sudan in ancient times; the other Nilotic Dinka, Nuer, and Anwak groups might well have been the same Ethiopian Sudanese of Aksum and Nubia; and the western African groups might well be related to the populations of the other regions. As Davidson realized, in the continent of Africa, “all these regions really belong together, and what is particular to each of them is general to them all in their foundation and emergence.”

An agrarian society, Sudanese society is strongly influenced by familial, religious, and ethnic affiliations as well as ideological and political orientations. Strong systems of extended family relations comprise a series of closely interrelated nuclear families all over the country, with each nuclear unit going about its separate business.

The cultural diversity of the country is characterized by peaceful alliances and intermarriages as well as social disputes that sometimes are caused by the strict system of ethnic classification. Experiencing a long history of ethno-regional relations across the border with Egypt and the non-African nations, Nubia and its Riverain people have categorized themselves into distinct groups based on *ahl al-balad*, the owners of land, *abid* or ex-slaves who still have

obligations towards ex-masters, and the *halab* whose descendants belonged to Upper Egypt. In the other parts of the country, “conflicts between the agriculturalists and the nomads or among nomads, farmers and migrant laborers are but a few of the daily cases heard at the different courts. Cases of land dispute include *harig* (setting fire to fields), *taadi* (vegetable garden and field trespass with intent to cause damage), and *juruf* (disputes over land on the river banks).”

The winds of social change, however, have been blowing vigorously over the rural side of the country. “Although the *muazzafeen* [public service employees] still respect the indigenous authority of *Aurs* [descendants of ruling families] and the *punuk* [the indigenous court], they are committed, at the same time, to enforce the regulations of the Damazin administration. Very often conflicts occur when administrative decisions interfere with cultural and local ties.”

At the present time, however, the question of Sudanese center-regional relations, rural development, and national identification constitute major political issues. The increasing consciousness of the Sudanese non-Arab, non-Muslim population about African heritage and the issues of national identification and religious tolerance motivated the need for anthropological and sociological research on the historical role that the Sudanese African cultures played to shape the Muslim tradition of the country, and the vital recognition of the diversity of Sudan in all spheres of political, social, and religious life. The Sudanese ancient African religions of many animist groups in the south and the Nuba Mountains might have mutually influenced popular Sufi life, as well as Christianity, with mythical interpretations and rituals. Perhaps the cultural heritage of the Sudanese communities was largely reflective of the multi-ethnic and religious diversity of the country more than any strict adherence to the Arab-Islamic models of the orthodox shari’a. Up to the establishment of the ‘Abdallab Arab dynasties and the Funj Muslim kingdoms that succeeded the Nubian Christian kingdoms of Sudan, the spreading of Islam was rather nominal under the direct influence of the Bedouins and the traders, who were not highly knowledgeable of Islamic jurisprudence. The Sufi leaders, like Qulam-Allah ben ‘Ayid and Hamad Abu Dannana, later on increased the dissemination of shari’a in the country. When the Funj consolidated their rule, they encouraged many jurists to teach Islam as a different faith from the Sudanese indigenous habits or Christian customs.

Among the majority Muslims of Sudan, the emergence and the growth of Sudanese modern political groups brought to life an ideological rivalry between the Sufi popular Islam and the formal tradition of Islamic jurisprudence, as well as conflict regarding the politics of separating state management from the political control of religious groups—an issue that had been largely initiated and pursued by Sudanese socialist and liberal parties, trade unions, and professional associations throughout the modern history of Sudan. In recent decades, a complete rehabilitation of Islamic jurisprudence has been placed at the top of the agenda for the movement to revitalize the Shari’a.

What possibilities would the Sudan’s cultural and religious diversity offer to help achieve national integration instead of authoritarian rule? Sudanese society has experienced multi-cultural interpretation and practices of Islam since the 7th century. In the post-independence era (1956 onwards), both civilian and military regimes exercised the pre-independent secularly oriented governance of the country. Applying an ethnocentrist Arab Islamic state by the Muslim Brotherhood groups since 1983, the succeeding military governments (1983–1985; 1989–2004) made serious attempts to indoctrinate the Sudanese political and religious liberality. These state intrusions failed to transcend the persistent African cultures that had earlier merged with the traditions of popular Islam, Christianity, and the much older African supernatural traditions to create the unique systems of Sudanese individuality, spiritual philosophy, national ideology, and liberal reality.

Sudan is a country composed of pluralist cultures that assertively defied authoritarian rule. The advancement of this popular mode relied on the observance of international human rights norms and civil freedoms, despite restrictions by recurring military regimes. Following the October, 1964 and the April, 1985 popular uprisings, the Sudanese political parties, military groups, trade unions, professional associations, and many human rights and civil society organizations agreed on the freedoms of organization and assembly as well as those of thought and expression to ensure civil and political rights, as a prerequisite of social stability and progression. This national contention prevailed among the succeeding transitional governments of Sudan that also witnessed a significant movement towards the realization of the right of self-determination to the largely non-Muslim

southerners and the other Muslims in the northern, western, and eastern regions of the country whose political and economic concerns were increasingly aggrieved.

Recently, the Sudan witnessed a massive flow of emigration, which included significant sections of the population, especially professionals and skilled workers. This occurred despite state-imposed strict measures to regulate emigration. The state's concerns with levels of aggregate investment, in essence, developed deficit monetization. New formulations of agricultural mechanization had earlier aggravated uneven development in the country, thus provoking massive migrations from the rural areas into urban centers. This further encouraged the brain drain, which developed as a consequence of unresolved strains in the individual, familial, national, and regional levels of interaction.

The international community and the regional entities of the African Union and the Arab League have collaborated closely with the American-led western powers to help the Sudanese make a just and permanent peace. The Niavasha Peace Protocols (2004) offered a viable opportunity to resolve Sudan's civil wars on the basis of flexible center-regional power and fair wealth arrangements. Still, the cultural realities of the country deserve careful attention by the next transitional government to augment the politically approved developmental consensus on the basis of stable national democratic consensus. In the light of the unabated cycle of violence in the south, Darfur, Nuba Mountains, and eastern Sudan, substantial revisions are needed on the part of the state in full collaboration with the opposition groups to advance popular participation in national decision making. Measures should be undertaken to rationalize the flow of national and international migration, reform educational programs, and promote the absorptive labor capacity of cities and rural areas in order to serve development and the nation-building of the whole country.

SUFI ISLAM

In most Muslim societies, pioneering Sufi mysticism taught the principles of Islam in a simple way by committing its disciples to a special moral and social order with a specific worshipping recitation based on the Holy Qur'an and the Hadith (the Prophet's sayings and deeds). "The Mawlawiyah ("Mevlevi" in Turkish), known to the West as the whirling dervishes, utilized the words and worldview of simple villagers, without using technical theological vocabulary, and thus they made divine truths accessible to those who were not literate or formally educated in theological Arabic or Persian." The Sufi leaders observed a life of austerity, piety, and spiritual influence. The disciples believed in the miraculous actions and the blessing nature of the Sufi as a *Walli* (saint) who must be strictly obeyed. The North and East African Muslim *Sheikh*, the *Marabout* of Senegal, and the other West African societies became a great spiritual force that often protected the poor and other powerless groups from the injustice of rulers. Sometimes, however, the Sufi would not strictly adhere to the formal shari'a (Islamic jurisprudence) in the striving to increase their non-Muslim followers.

Since medieval times, many African and Asian indigenous cultures were incorporated into the Muslim Sufi tradition. Kings, chiefs, maharaja, or sultans believed in the supernatural powers of the Sufi *Walli*. In continuity with the ancient dancing parties of old deities in Africa, the *turuq* adopted necessary changes to ensure the monotheist meanings, ablution, and recitation of the Qur'an. In the post-Christian Nubia, the Sufi *Wali* or his successors assumed the privileges, high esteem, and miraculous expectations of the Christian saints to facilitate the difficulties of life for the Bedouins and the peasants. This helped Sufi teachings, rather than the formal shari'a, to merge with the old mythology and folklore.

These accounts of early Islam indicate a unique liberalism of the Muslim community under the flexible teachings of the Sufi tradition. The Sufi orders often separated the spiritual leadership of society from the authority of the state. The rulers would not initiate state projects without Sufi advice. With this prestigious status, many Sufi leaders collaborated closely with the ruling groups to maintain stable social and religious relations with their believers. Many colonialist and post-independence governments encouraged the Sufi influence in Middle Eastern and African societies to avoid the engagement of Islamic jihad (holy war) in state politics. The Sufi leaderships accordingly enjoyed prestigious political and economic positions in collaboration with the governing groups.

SUMERIAN CIVILIZATION

Sumerian civilization began in the flood plains between the Tigris and the Euphrates rivers. Deep beneath the land that now covers most of modern day Iraq lies the ancient country of Sumer where Sumerian civilization thrived. It covered approximately half of Mesopotamia. From 3500–2000 BC, this civilization flourished in the Mesopotamian land where the first cities began.

The Sumerians were the first civilized people to maintain a writing system called cuneiform (meaning curved lines). With this invention, the Sumerians were able to record literature, common laws, and business transactions and eventually created educational systems to teach cuneiform writing. The Sumerians gave the modern world a legacy of inventions, including agricultural and irrigation methods, weights and measures, the wheel, and the

plow. They created the first city-state known for its architecture and its complex political, social, and economic structure that organized a legal system, labor practices, trade, and burial rites.

For thousands of years, cuneiform writing was the only writing system available to humans. At first, writing was developed to help govern trade and other business transactions. Later, people needed a way to identify themselves for business matters. Craftspeople developed pottery seals that, when rolled in moist clay, left behind a unique design or signature.

Writing quickly grew into a way of recording mythology, poetry, literature, mathematics, and historical events. For example, the legendary and much exaggerated tales of Gilgamesh were written in cuneiform. Gilgamesh was a mythical Sumerian ruler who possessed superhuman characteristics and engaged in fierce battles with ferocious animals. In fact, an epic tale of Gilgamesh tells of a great flood and is strikingly similar to the story of the flood in the Old Testament.

Cuneiform writing also enabled law codes, royal decrees, and court rulings to be recorded, preserved, and passed down through generations. The Sumerian King List, a chronology of legendary kings, is an historic example of this Sumerian legacy.

Writing was a skill that demanded great dedication and painstaking practice. Education became organized as children learned to read and write in cuneiform. The first schools resulted and children of only the wealthiest families attended them. At first, the purpose of school was to learn how to be scribes who could read and write cuneiform. However, in time, students began to study the sciences as well.

Despite the lack of adequate or consistent rainfall, Sumerian civilization was agriculturally based because the Sumerians developed an irrigation method. They dug canals that brought water to their farming fields. The Sumerians became skilled farmers, credited for inventing the plow to till the soil. Their chief crops were barley, wheat, and grains. They also grew peas, onions, lettuce, grapes, and figs. They raised sheep, cattle, and goats for milk, wool, and meat. They fished the abundant rivers and hunted an occasional antelope, gazelle, deer, or wild bull as a much-appreciated special treat.

As agricultural processes became more efficient, crops and livestock became plentiful. An array of specialized occupations emerged as some Sumerians were able to leave the farm and take up specialized crafts. Merchants, teachers, priests, physicians, musicians, poets, scribes, and tradesmen existed in addition to farmers and fishermen. Other Sumerians created weapons, cloth, and pottery. In fact, the first wheel ever invented was used as a pottery wheel. Further advances in the use and design of the wheel included turning it on its side and creating open spokes. This eventually created not only wheeled wagons but later in Mesopotamian history, chariots that would be used in battle.

As more people settled into Sumer, the need for buildings increased. Sumerians built homes, religious temples, and eventually, defense walls around their city-states to protect them from warring neighbors. Naturally, some citizens became skilled builders.

Because wood and stone were scarce and unsuitable for building, clay became the main building material. Sumerians made clay bricks that were cemented together with asphalt. Common citizens lived in small houses of two or three rooms with no windows. Wealthier families lived in two-story houses with the first floor used for servant quarters and meal preparations.

Not only did the Sumerians build homes, but their legacy includes impressive and elaborate buildings called ziggurats. These huge houses of religious

Source: © FreeStockPhotos.com.

worship were towers built with terraces. Each level was smaller than the one below and the walls inside were elaborately decorated.

The processes of irrigation and building required maintenance and cooperation of the Sumerian citizens. Rulers emerged to organize labor and send out traders to seek materials like wood and precious metals and stones, which were not readily available in Sumer.

All this change led to a growth in population and created a more complex lifestyle. The most populous areas were the city-states. The political structure of Sumerian civilization was different from other societies because their communities were fashioned into independent city-states that were originally organized around a temple and a priesthood. The earliest rulers of city-states may have been called an “en,”

meaning “high priest.” They would have been a representative of the local god and responsible for managing the temple lands and the people entrusted to work on them. As societies grew more complex, a second office of leadership, called an *ensi* or “governor,” emerged to manage civic affairs such as law and order, commerce, trade, and military efforts. In time, the people democratically selected leaders to rule in times of war and peril. These leaders, called *lugals*, meaning “great man,” oversaw civil, military, and religious functions of the city. The office of *lugal* seemed to emerge at a time when defense walls were first constructed. It was customary for an elected ruler to step down and return to his place in society after a military crisis ended. Over time, however, the constant threat of war created a need for rulers to remain in power for longer periods of time. Eventually, rulers served for a lifetime, passing rule to their sons as successors to a king’s throne. As a state of dynasties had taken root, kings and royal families emerged.

Kings wrote and enforced local codes of law and, in Sumerian civilizations, legal matters were settled in courts of law. Three to four judges, who were often honorable men of the community, heard disputes. Much like the courts of today, evidence could be presented and witnesses gave sworn testimony. Perjury was punished by divine retribution because the gods would curse liars. However, decisions were not legally reversible because there was no process for legal appeal in Sumerian courts.

The most famous Sumerian city-states were Uruk, Ur, Eridu, Kish, Lagash, and Nipur. What we know today of these city-states comes from archaeological digs.

The glorious city of Ur, during the Third Dynasty of Ur dated at 2112–2004 BC, was an important center of Sumerian culture. Ur is identified in the Bible as the home of Abraham. The city’s proximity to the Persian Gulf made it an important seaport because southern Mesopotamia relied on trade for hardwoods, precious metals, and stones.

Archaeologist C. Leonard Wooley discovered what we know about Ur in the 1920s and 1930s. He found burial sites dating to 2600–2000 BC. The most common and simplistic sites had the deceased rest on their sides, as if they were asleep. The burial site contained a few personal possessions and ceramic bowls and jars for food and drink. Other more elaborate gravesites contained substantial quantities of goods, vehicles, and personal and household servants.

Although Wooley suggested that royal attendants drank poison and died willingly for their sire, the exact methods or reasons for these sacrifices are unknown. Sumerians buried their dead with possessions that the dead might want or need in the afterlife. For the wealthy or royal family members, this would also include servants and other members of the household staff.

After 1900 BC, Sumer would be overtaken by the Amorites and Gutti, tribes from Elam. Sumer would never regain political domination and the whole of Mesopotamia would remain a warring land until the rise of Babylonia under Hammurabi, who would once again regain the region’s glory.

SUMNER, WILLIAM GRAHAM (1840–1910)

William Graham Sumner, a founder of sociology and a brilliant anthropological theorist of normative order, was strongly influenced by the writings of the British evolutionist Herbert Spencer.

Sumner was born in Paterson, New Jersey on October 30, 1840. He studied political economy and graduated from Yale University (1863). He studied French and Hebrew at the University of Geneva in Switzerland, ancient languages and history at Gottingen University in Germany, and Anglican theology at Oxford University. Following his ordination as an Episcopal priest (1869) and his service at parishes in New York City and Morristown, New Jersey, he was appointed professor and chair of political and social science at Yale (1872).

Having established a very visible, natural reputation as a professor spotlighted by his economic theory of individualism, private property, and laissez-faire in opposition to tariffs, socialism, and social reform movements in the 1870s and 1880s, Sumner became

interested in the evolutionary theory of Spencer and primary natural laws and adopted Social Darwinism while abandoning the study of political economy for sociology. He transformed his life's work from popular lecturer, essayist, and polemicist to objective sociological researcher and scholar, teaching the first course in sociology (the "science of society") offered in the United States. He employed ethnographic methodology in his research and conceptualized a classificatory schema of tribes and peoples with their characteristics that was later established by G. P. Murdock as the Human Relations Area Files.

Sumner's major works include *Socialism* (1878), *The Forgotten Man and Other Essays* (1883), *What Social Classes Owe to Each Other* (1883), *War, and Other Essays* (1894), *Folkways: A Study of the Sociological Importance of Usages, Manners, Customs, Mores, and Morals* (1906), *Earth-hunger and Other Essays* (1913), *The Challenge of Facts, and Other Essays* (1914), and *The Science of Society* (with A.G. Keller, 1927).

Folkways is an anthropological and sociological classic. Sumner knew the power of words (he was fluent in 14 languages), and he chose his words very carefully. By inducting from ethnographic and historical materials, he shaped a model of sociocultural evolution and examined folkways as people's customary acts, which evolve toward uniformity and social institutions. As such, folkways became the means of adaptation to social conditions; they are the acts to satisfy people's needs of maintenance, protection, perpetuation, and security.

Folkways are conventional customs for appropriate behavior. Those folkways that are judged to be necessary for societal welfare become mores (and institutionalized as laws) where violations and commensurate sanctions (social control punishments) exert coercion for compliance. Those mores considered ethical principles constitute morals. To Sumner, the social grid of folkways, mores, and morals make normative social order possible and produce universal institutions: people will conform to the "norms" because they are right and their violation constitutes taboos and results in severe punishment. Sumner perceived the tendency of folkways and mores to evolve as a people adapt to meet their needs.

Sumner's other contributions include the concepts "ethnocentrism," "in-group" and "out-group," a dynamic conceptual model of social institutions ("crescive" and "enacted"), the theoretical underpinning of sanctions and social control, and, above all,

principles upon which a compendium of ethnographic material can be utilized in the "science of society."

Sumner died on April 12, 1910 while in midstream of his life's work. His theory of unilinear evolution failed to incorporate Spencer's theory of dynamic change, resulting in rejection by anthropologists and sociologists. Nevertheless, his contributions are significant and influential, perhaps the classic work of American anthropology and sociology, and hold promise for the emergence of a "science of society."

The term "superorganic" was probably first used by the early sociologist Herbert Spencer in the late 19th century, in contrast to "inorganic" or "organic." To Spencer, and other cultural-determinist sociologists and philosophers like Émile Durkheim and Auguste Comte, human society is superorganic in that it exists at a higher level of complexity than physical things or biological organisms. Viewed through Spencer's social evolutionary thought, superorganic refers to the claim that culture is an entity that exists over and beyond the individuals that make it up. That is, just as inorganic entities (such as rocks) and organic biological entities (such as plants) have real ontological existence, so does the super- or meta-force of culture.

The notion of the superorganic was brought into anthropological discourse in 1917 in a debate between two of the most influential figures of the time, Alfred Kroeber and Edward Sapir, in the *American Anthropologist*, the premier journal of the day. Both were students of Franz Boas who, as a literal founding

father of American anthropology, spent much of his career wrestling to understand the relationship between the individual and culture. To Boas, it became clear that the individual—both as recipient and beneficiary of culture, but also as its carrier and creator—was primary.

Kroeber, as did all Boasians, rejected the notion that culture was biological, or something that humans inherited. Neither were there any superior or inferior cultures, either in intellectual potential or social advancement. He parted paths with Boas, however, when he argued that humans are trapped in the web of historical and cultural forces. As Kroeber said in his seminal article, it is tempting to leap from the individually mental to the culturally social, but are we justified in doing so? Every schoolchild today knows much more than Aristotle, but even a thousand of them cannot match his impact. This is because all knowledge is social, and “it is knowledge, not the greater development of one individual or another, that counts. . . . A super-Archimedes in the ice age would have invented neither firearms nor the telegraph.” This is obviously a recasting of the Great Man theory of history for an anthropological audience. But to Kroeber, the superorganic was actually what made anthropology a science—with its subject matter being the universals and regularities of human behavior as mediated, if not completely dictated, by the forces of history and culture. And it simplified anthropology’s task immensely, by eliminating human decision making from the analytical equation.

Sapir disagreed with this dismissal of the individual and questioned the whole superorganic premise. First, he considered the analogy of social phenomena to the development of inorganic to organic processes to be false. We what we call the social is only a *selection* of the phenomena that is reducible to inorganic or organic processes and is not some new abstract force. When we talk about culture we are only talking about an abstraction culled from the observations of individual behavior, after all. He also argued that the “laws” of history or sociology are only rarely generalizable and almost never predictive. And finally, he asks where the laws of the superorganic apply: at the level of the individual person, or the group? If it is at the group, which group: “a clan, a language, a priesthood?”

The superorganic is still actively debated in anthropology, though usually manifested in different

discourse. Leslie White—with his evolutionary view of culture and notion of “culturalogy”—is just one notable example. And under the influence of post-modernist theories of culture, this dialogue will no doubt continue.

—James Stanlaw

SURVIVALS, CULTURAL

Toward the end of the colonial era, there seemed an imperative to collect, record, and catalog as much about the disappearing cultures encountered by colonial Europe as possible. From the perspective of the 19th-century traveler, government official, and academic, it seemed that cultural traditions were rapidly becoming extinct following the perceived lure of the modern world to those living in a traditional world. Cultural survival seemed impossible.

The mindset predominant during this era framed these cultural worlds in a “pre-” and “post-colonial” context. To the European, a pre-colonial world contained cultural traditions “found” by the civilized world to be in a kind of timeless equilibrium. The concept of “tradition” as something close to static and unchanging became a pivotal marker distinguishing these cultures as they were before colonial “discovery” and after. However, one has to question this notion of “tradition” and examine more closely what it implies in the context of cultural survival. Was it really the tantalizing “gifts” of the modernizing world seducing peoples of other cultures to

abandon their cultural traditions in such a way that survival became an issue?

The survival of a culture may be threatened by the imposition of other cultural forms that significantly alter existing forms and belief systems. Religious conversion is an example that is readily found in many examples of threatened cultural survival. Loss of language poses a further threat to a culture's survival, given the unique ways in which culture is expressed and transmitted through language. Further, the inability to pursue one's livelihood may have a detrimental effect on cultural survival. To herdsman of the cattle cultures in eastern Africa, the removal of cattle from their care severely disrupts their view of the world and themselves within it. Cultural survival is threatened when the central focus of that culture is destroyed.

Of a more extreme nature, cultural survival becomes a major concern when a population decreases to such an extent that significant institutions can no longer be maintained. A classic example is the once prosperous Mandan Indians of North America. In the middle of the 18th century, an estimated 9,000 Mandan lived along the upper Missouri. Significant ritual activity required large numbers of Mandan participation. When waves of smallpox epidemics swept through the villages, these rituals could not be performed due to the sheer loss of life. The epidemics eventually diminished the population to approximately 63. Under such circumstances, cultural survival is extremely difficult, if not impossible.

People have always negotiated cultural change as new ideas, opportunities, or changing circumstances have arisen. Borrowings and reconfigurations of "other" ways of doing things have been an aspect of human culture from the beginning. The concept of survival is not an issue when these processes occur gradually and with the full involvement of the people in question. However, when this is not the case and change is imposed by outside forces (and sometimes inside forces brought about by revolution), cultural survival becomes an issue. The central questions are "What do we mean by survival?" and "What are the conditions that affect the way one culture 'survives' better than another?" "How does one measure 'survival'?"

— Shirley F. Campbell

Swahili (more properly *Kiswahili*) is in the Bantu family of languages that dominate most of sub-Saharan Africa. It is used as a first language by about five million people along the East African coast from Mozambique and the Comoro Islands to Somalia. More important, it is used as a lingua franca (in the form of nonstandard sociolects) by more than 30 million people in the interior, even into the Congo basin. It has a standard form, based on the Zanzibar dialect *Kiunguja*. This standard form, in roman script, is an official language of Kenya and Tanzania. It has also become widely taught in the U.S. as the "African" language, partly due to anglophone East Africa's accessibility to American scholars and partly to its adoption by African Americans for African heritage celebrations such as Kwanzaa.

Swahili is similar to other Bantu languages, with a system of noun classes whose prefixes occur linked in concord paradigms with other phrasal constituents. Thus, *yule mtu mmoja mkubwa* (lit: that person one large, "that one large person"). Verb inflectional affixes include subject, object, tense prefixes, and voice and aspect suffixes. Stems are often made from a syntactically unmarked root and a derivational suffix. However, unlike most Bantu languages, Swahili lacks tone as a distinctive phonemic feature. Lexically it is marked by many Arabic loans, so much so that some have portrayed Swahili as "Arabic" even though these have been modified into Bantu forms. The Arabic stem *k-t-b* (e.g., *kitab* "book," *kutub* "books") has become the Bantu noun stem plus prefix of *ki-tabu* "book," and *vi-tabu* "books." (Indeed, *Kiswahili* itself is similarly based on the Arabic *sawāḥil*, "coasts.")

What is significant about Swahili is not its structural features so much as its varying sociolinguistic conditions. In the early 19th century (after hundreds of years as the language of the coastal mercantile

ports), it became the lingua franca of slave and ivory caravans from the coast to the interior. European colonial administrators, in turn, adopted it as the language of native affairs, required it for jobs, and supported its standardization, thereby providing it some degree of prestige. However, missionaries had ambivalent views in regard to its development. These ranged from supporting ethnic vernaculars in order to proselytize in a first language rather than in a “Muslim” second language, supporting Swahili as the language of a native church (much of the standardization was accomplished by missionary linguists), and supporting English instead as the language of a Christian African elite. With independence, and the desire for national symbols, Swahili was viewed as an alternative to either English (a medium of former colonial control) or an ethnic vernacular (a potential for exclusive ethnic privilege and exclusion). Tanzania made it their national language and developed it as a medium of post-primary instruction as well as national legislative and legal affairs. Kenya kept it as an official language along with English. English still occupies a position of dominance as the language of wider opportunity and education, and the challenges and prospects of developing Swahili to displace, or at least draw even with, English constitute an absorbing issue in language planning. For example, many pro-Swahili activists hold that some actions must be taken to slow the growth of English forms into Swahili.

capacity that allows advanced primates to have culture and to communicate their cultural concepts. Although they are used as synonyms, as verbs “symbolize” and “symbol” differ: to symbolize means to use existing concepts as symbols, and some higher nonhuman primates demonstrate this ability. To symbol means to symbolize, but also to create new symbols, a capacity of people but not yet convincingly shown to exist in apes and monkeys. In its most general usage, as representation and embodiment of meaning, and by the recognition that many cultural symbols are unintelligible separate from their cultural contexts, in the late 20th century the symbol became the focus of a specific field of anthropology: symbolic anthropology.

The term symbol is used popularly as synonymous with any of a variety of simpler forms of representation, for example, a sign, icon, or emblem. In fact, the symbol can do all that those forms can do, but it can do more: it not only represents, stands for, a thing or action; conceptually, the symbol can take on certain properties of its referent, and thereby it can stand in for, take the place of, the thing it represents. The symbol can be complex, embodying different levels of meaning, and even quite different realms of meaning, and displaying the quality sometimes known as “multivocality.” The symbol can convey different meanings simultaneously, within the same communicative context, or in different contexts.

Also, the symbol may or may not bear any resemblance to, or have any intrinsic association with, its referent. This becomes clear when we understand that words are symbols. The concept of abstract speech and thought is of the same order as symboling. Leslie White's famous 1949 example of holy water (in *The Science of Culture*) illustrates the capacity, and complexity, of symbolic meaning. The unique capabilities of human culture are perhaps best demonstrated through religious ideas, and these semantic capabilities of the symbol are at the very core of religion. Raymond Firth observed in his 1973 work, *Symbols, Public and Private*, that “the relation [of the symbol to its referent] is such that the symbol by itself appears capable of generating and receiving effects otherwise reserved for the object to which it refers—and such effects are often of high emotional charge.” This illustrates the amazing strength of the symbol: the symbol can take on the very qualities of whatever it represents, and if its referent has power, then the symbol itself becomes powerful. The concept of powerful

SYMBOLING

In its simplest definition, a symbol is a thing or action that represents another thing or action, and anthropologists agree that symboling is the unique cognitive

symbols is at the very core of religion, and is the means whereby magic is enacted. Religious symbols, such as the Christian cross, have power and are used protectively as amulets. Reproductive power is extremely strong, and objects representing the vulva, such as cowries, or the penis, such as horns, are ancient and widespread symbols of power. Some symbols transcend cultural boundaries and may be universal, such as eggs, horns, or the color red; most symbols are understandable only within their specific cultural/linguistic context.

Culture is recognized as a system of meaning, and each symbol is at once the locus and the vehicle of meaning. The social science focus on symbolism received strong stimulus by C. K. Ogden and I. A. Richards's *The Meaning of Meaning*, published in at least eight editions from 1923 through the 1940s. In the latter 20th century, a convergence of various influences—Freudian psychoanalysis, principles of linguistics, French structuralism, and the focus on symbolic meaning—gave rise to a new emphasis within cultural anthropology, the field of symbolic anthropology. Sigmund Freud's psychoanalysis taught that certain unconscious drives and influences are revealed through the careful examination of certain conscious modelings and expressions, through his famous principles of displacement and condensation. Much of Freud's reasoning has been dismissed, but he laid the foundation for recognition of basic cognitive dynamics and the nature and role of symbols in human consciousness. The study of linguistics expanded on understanding of the structure and processes of cognition; words embody meaning in culturally unique ways and, as explained by Edward Sapir and Benjamin Lee Whorf, certain linguistic constructions can influence perception and human action. Linguistics provided the framework for a very painstaking mode of investigation into meaning, the field of ethnoscience, in the 1960s. Structuralism, particularly as expressed by Claude Lévi-Strauss, drew from certain principles of linguistics and semiotics—the study of signs—to reveal further patterns of cognition. Lévi-Strauss' delineation of apparently universal cognitive dichotomies, such as culture/nature, village/bush, east/west, right/left, sun/moon, male/female, sacred/profane, stimulated new and

Source: © iStockphoto/Dor Jordan.

exciting ethnographic analyses of specific cultural, spatial, and cosmological constructions both within and beyond anthropology. And the recognition by certain anthropologists, notably Victor Turner and Sherry Ortner, of what Ortner called “key symbols” in culture helped to stimulate anthropology's concentrated focus on symbolic meaning.

Symbolic anthropology became an American emphasis by the 1970s, though it had parallel emphases in Britain and Europe. Two of Turner's works, *The Forest of Symbols* (1967) and *The Ritual Process* (1969) became classics. Turner came to focus on ritual as a stereotyped and formalized enactment of social drama, symbolic of many layers and complexes of meaning, “themes.” His concepts of the appositions of structure and “anti-structure” and his application of Arnold van Gennep's notion of “liminal” states, were influential beyond anthropology. Clifford Geertz' widely-cited essay, “Religion as a Cultural System” (1965) defines religion as “a system of symbols.” His concepts of “deep play” and “thick description” were also widely influential (it is interesting to note that outside of anthropology, Geertz' use of the phrase “deep play” was misunderstood and has been variously applied and interpreted, including in terms of his “thick description,” as a phenomenon whose full meaning is revealed only after careful dissection of convoluted layers of meaning). Geertz was arguing that—contrary to earlier anthropological premises, especially the premises of ethnoscience—cultural meaning is not deep in people's heads but is public, communicated,

and expressed in symbols, and can be adequately interpreted by outsiders.

Symbolic anthropology as a separate field of emphasis was criticized for several reasons. By isolating and focusing on symbols, even symbolic complexes, it tended to lose sight of their relationship with other dimensions of culture, to homogenize differences within a culture, and to emphasize and even exaggerate them beyond their importance within their cultural contexts. Theorists with Marxist or other materialist bent complained that by emphasizing the conceptual, symbolic anthropology lost sight of the structural and the material, both of which are critical in explaining social conduct. And, it might be noted, for heuristic purposes anthropology breaks down various institutions of culture and regards them as lenses through which the cultural system may be viewed, and so we have social anthropology, ecological, economic, political, legal, religious, and so on, a theoretically endless string of anthropologies. It might be argued that symbolic anthropology probably could not last for long as a separately demarcated field because it is tautological; culture *is* symbols.

But symboling may again emerge as a central focus for anthropological study, prompted by the recognition of a likely biological basis for this universal human capacity. In his 1975 book *Rethinking Symbolism*, Dan Sperber had suggested that symbolism may be rooted in inherent aspects of human cognition. Such suggestions are being confirmed today by modern developments in neuroscience, which have indicated cortical bases for that very fundamental primate cognitive capacity: imitation. Experiments by Marco Iacoboni and his colleagues at UCLA have shown that specific areas of the human brain are involved in subjects' imitation of actions, both when the stimuli are actions, and when they are symbolic representations of actions.

SYNCRETISM

Syncretism is defined as any attempt to reconcile disparate—and sometimes opposite—beliefs and practices. It represents a blending of schools of thought and is often associated with establishing analogies between two or more discrete or formerly separate traditions. Most academic studies of syncretism focus on the blending of religion and myths from various cultures. Viewed positively, syncretism seeks underlying unity in what appears to be multiplicity and diversity. It is common in language, literature, music, the arts, technology, politics, social organization and kinship, and economics. Anthropologist Jonathan Friedman has also suggested that the term syncretism may be useful in the study of social organizations, material culture, and processes of localization and globalization. Viewed negatively, syncretism is a contentious concept and has undergone many transformations. Among some religious leaders, for example, the term syncretism often implies impurity or contamination. Disagreements center on the word itself and on the history of its applications.

Contemporary celebrations of Christmas, Easter, and Halloween offer examples of syncretism in practice. Syncretism is not a new phenomenon. The ancient Romans adopted pagan Yule traditions that eventually made it into Christmas celebrations (Christmas trees, Yule logs, and the like), and Roman Catholics in Central and South America integrated elements from indigenous Latin American and North American religious traditions.

The Ancient Greek prefix “*syn*” means “with” and the word “*krasis*” means “mixture.” Thus, the term “*synkrasis*” meant “a mixture or compound.” The Greek words *συνκρητισμός* (*synkretismos*) and *συνκρητίζειν* (*synkretizen*) do not appear in classical literature until the time of Plutarch (AD 45–125). Plutarch used a political meaning of the term in an essay titled “On Brotherly Love” (*Peri Philadelphias*),

which appeared as a chapter in his *Moralia*. In searching for the origin of the word “syncretism,” Plutarch claimed to have found an example of syncretism in the Cretans, who reconciled their differences and came together in an alliance whenever they were faced with an external threat. He labeled this coming together as “their so-called ‘syncretism.’” For Plutarch, syncretism was not only a testament to political expediency but also fostered peace and brotherly love. Greek culture was a mixture of Persian, Anatolian, Egyptian, and later Etruscan-Roman elements into an overall Hellenic framework.

Throughout the 19th century, overt syncretism in folk beliefs was seen as a strong indication of the cultural acceptance of alien or earlier traditions. By the end of the 19th century, however, identities were no longer predicated on the existence of continuous and immutable cultures, and the concept of syncretism came to the forefront largely because it blurred local distinctions—a characteristic that made it useful for the rulers of multicultural nation-states. At the same time, the rejection of syncretism or “anti-syncretism” in the name of purity or orthodoxy helped to legitimize a desire for cultural unity.

Among American anthropologists, the term syncretism is most closely associated with Melville J. Herskovits, who is best known for his research on the survival of African cultural traits among blacks in the Americas. Herskovits advocated an appreciation of what he called “syncretized Africanisms” and focused on various types of “acculturation” in order to address more general issues of culture contact. Syncretism is apparent in New World religions such as Brazilian *Candomblé*, Haitian *vodun*, and Cuban *Santería*. These religions analogized various Yoruba and other African gods and selected Roman Catholic saints. Perhaps the most syncretized New World religion is Brazilian *Umbanda*, combining African deities, French spiritualism (*Kardecismo*), local aboriginal spirits, African and Hindu deities, and North American aboriginal leaders.

In *The African Religions of Brazil*, Roger Bastide attempted to account for syncretism by stressing historical processes like conquest and migration. He traced the various ways in which African, European, and aboriginal religions have come together in what he termed an “interpenetration” of civilizations. Rather than offering a psychological explanation, Bastide focused on groups of people who were differentiated by sex, social class, and age. By contrast,

Stephen D. Glazier’s research on the Spiritual Baptists in Trinidad focused on individual Baptist leaders and their practice of borrowing rituals from a variety of religious traditions but keeping these borrowed rituals separate in time and space. According to Glazier, one outcome of this process is a religion that is marked not so much by syncretism as by a dynamic juxtaposition.

Studies of syncretism in South Africa have focused on African Independent Churches (AICs). Anthropologist J. Y. D. Peel cogently argued that syncretism was not central to AICs because these churches represented reinterpretations of Christianity but never encouraged a mixture of Christianity and tribal elements.

In general, anthropologists have regarded the term “syncretism” favorably. Yet Stewart and Shaw report a growing uneasiness with the term among anthropologists who have been influenced by postmodernism. A major contribution of anthropologists has been to demonstrate that syncretism is not inevitable. It is possible, for example, for two groups to live in close proximity and largely ignore each other. For this reason, anthropologists find it both necessary and informative to examine syncretism with respect to relations of power. In *Syncretism and the Commerce of Symbols*, Goren Aijmer dramatically shifted the focus of research by asking, “Under what specific conditions do people in any one group pay attention to the cultural symbols of another group?” Aijmer concluded that syncretism is most intense whenever the inequality between cultures has been the most pronounced. Equally important, war, conquest, colonialism, trade, migration, and intermarriage bring syncretism to the forefront. Race, gender, age, and social class are also factors. He suggested that scholars must examine the relationships between global and localized syncretism. Are two or more religions influencing one another equally or is one dominating the rest? How does syncretism relate to issues of entrepreneurship and to theories of modernization?

It should be emphasized that authenticity and originality are not always dependent on the alleged purity and uniqueness of religions and that many so-called “original” religions are the result of a unique syncretism that has not occurred elsewhere. Researchers need to become sensitive to the ways in which people negotiate and redefine the boundaries of their ideas and practices. Shaw and Stewart underscore the need to examine problems of agency, especially when

agency is ascribed to religious traditions without reference to religious specialists.

At times, syncretism is seemingly intentional, while at other times it is largely unintentional. There are always unexpected consequences. It is imperative for scholars to chart the increasingly complex interconnections between syncretism, social change, and resistance. Stewart and Shaw concluded their study of syncretism by suggesting that the term be recast as “the politics of religious synthesis.” A major focus, they postulated, should be on “anti-syncretism” and the antagonisms shown by agents who are largely concerned with the defense of religious boundaries.

TABOOS

Taboo is a concept that originated in a very specific cultural meaning and became generalized in popular English. Popularly it means forbidden and to be avoided—by custom, or because of some danger, or under some general supernatural sanction, or by explicit divine order. But in anthropology, it has much more specific meaning. Based in the universal idea that all things have an inherent mystical power of some sort, taboo means the avoidance of a specific behavior for fear of harm by a dangerous power, or of dangerous pollution caused by the intermixing of incompatible powers. Taboo circumscribes some kind of supernatural threat that is usually simply termed “danger.” Some tabooed acts might have horrendous society-wide consequences; examples are incest, culturally defined but universally forbidden, or severe forms of sacrilege. But most taboos are sanctioned by some specific consequence, most commonly infection by some powerful mystical force, which can cause psychological or physical sickness, or some reversal of personal fortune, to the offender or to those close to him. Such infection may be termed pollution, or contamination, or defilement; it renders the offender impure or unclean, and such impurity or uncleanness is contagious, so the offender should be somehow isolated until the contagion has dissipated or a cleansing ritual of some sort has been performed. Examples of widespread taboos include entry by members of one sex into areas or activities restricted to the other; entry into certain adult activities by children, or into sacred areas or activities by uninitiated or otherwise profane persons; entry of objects associated with wildness or violence and death, such as weather gear, weapons, or butchering instruments, into areas demarcated for

peace, socialization, healing, or sacred activities, such as the home, hospital, or temple; performance of acts involving tying or cutting or closing, or symbolic representations of any of these, by pregnant women; committing incest; physical contact with people with various sorts of bodily lesions, or with menstruating women, or with corpses; exposure of the adult genitals; and various magical activities. In such senses, taboos are culturally universal, and the concept has important implications not only for ritual behavior but for social and political organization.

The term was first introduced into European and American awareness by Captain James Cook after his Polynesian voyages and investigations of 1768–1779. It was recognized as having universal parallels by James George Frazer in the ninth edition of *The Encyclopedia Britannica*, 1875–1889. In Polynesian languages the term meant forbidden, as in a simple injunction, but it also meant sacred, and it involved a ritual prohibition enforced by a specific kind of supernatural sanction. In Polynesia and Melanesia it was defined in terms of *mana*, a communicable power innate in all things. Mana occurs in varying types and degrees of intensity, and in certain concentrations its different forms should be kept apart, lest some misfortune occur from their intermixing. Most mana is positive, like that of chiefs or benevolent spirits, but it can be overpowering to ordinary unprotected people, resulting in sickness or even death. It is similar to the concept of the sacred, which should be approached and handled only by sacralized priests; contact by ordinary people can pollute the sacred and endanger the offender. But mana can also be negative, even evil, like that in demonic spirits or corpses, or the malicious magic of sorcerers, and it is contagious, from initial to secondary contact, and a contagious person is isolated until the appropriate cleansing rite has been

performed. Early ethnologists of Polynesian belief and custom gave three prominent examples of taboo acts by ordinary people: touching chiefs, corpses, or newborn babies, but it should not be assumed that the resultant afflictions are identical. The English word “taboo” derives from the Melanesian and Polynesian variants *tapu*, *tabu*, or *kapu*, meaning having a dangerous quantity or type of mana, but like mana, the nature of taboo varies considerably throughout Melanesia and Polynesia.

Explanation of taboo has proved challenging throughout the history of anthropology. Explanations based in rationalizations of sensible prohibitions—avoidance of sexual relations among close kin or of eating dead flesh—quickly proved unsatisfactory. Early scholars saw in taboo a supreme example of the “irrational” in primitive culture. Captain Cook asked the men why, since they enjoy the company of women, it was *tabu* to eat with them; their answer was simply that it was their custom, and the custom was right. Indeed, the complex and widespread system of taboos in Hawai’i was seen as so cumbersome in the context of modernization that it was publicly violated and abrogated by King Kamehameha II in 1819. Less than a year after its abolition, most of the system was recorded by the missionary William Ellis in his four-volume *Polynesian Researches*. Taboo was quite early recognized as reinforcing patterns of respect and authority in Polynesia, and subsequently it has been seen to have important social, political, and cosmological functions.

It is a magical concept; the magical act involves establishing an active mystical connection over a distance. Magic most often involves the principles of similarity and contact; things which appear or behave similarly, or which have been in contact with each other, have a causal connection. Frazer in his *The Golden Bough* identified taboo as “negative magic”; it means avoiding the establishment of a magical connection by avoiding imitation of or contact with something. Sigmund Freud famously placed the origin of the taboo concept in the Oedipus complex, in *Totem and Taboo* (1913).

Émile Durkheim saw taboos as among a larger class of “interdictions” necessary to maintaining separation between the sacred and the profane. A. R. Radcliffe-Brown, in his famous Frazer Lecture on Taboo (1939), asserted that, as first observed by Frazer, taboos provide supernatural enforcement for the rules of society, and that these social results

of taboos “constitute their essential function and the ultimate reason for their existence.” Lucien Lévy-Bruhl offered similar interpretations in his various efforts in the 1930s to show how patterns of social organization develop out of patterns of thinking.

The concept of supernatural danger seems to have been recognized first by Frazer, and subsequent scholars have recognized its social implications. Mary Douglas incorporated it into the title of her great work, *Purity and Danger* (1966). Therein she surveyed many fields, examined instances of ritual avoidance in the Hebrew scriptures, especially *Leviticus*, and following the functionalist explanatory tradition in anthropology, she showed that taboos underpin social structure everywhere. Douglas further interprets taboo as functioning in a critical system of social and cosmological classification, serving to keep things of different orders and classes separate from one another. The apparently universal village-bush or culture-nature dichotomies recognized by Claude Lévi-Strauss are strengthened and maintained by taboo, for example, Lele taboos against bringing fishing equipment into the village. Nature is wild and chaotic, culture is calm and orderly, and the classic principles of sympathetic magic explain how things that have been in contact with things or states retain the qualities of those states when separated from them. Many well-known “superstitions” can be similarly explained, for example, early warriors were forbidden to bring armor into the home; world religions forbid bringing weapons into places of worship; and western European heritage has superstitions about placing hats on beds or opening umbrellas inside the home.

Tahiti is part of the Society Islands, a group of 11 major islands and numerous smaller islets in the South Pacific also commonly referred to as French Polynesia; these islands are included geographically as part of East Polynesia by archaeologists. Tahiti is one of the windward isles of the archipelago, along with Maiao, Me'etia, Mo'orea, and Tetiaroa; the leeward isles include Huahine, Maupiti, Porapora, Ra'iatea, Taha'a, and Tupai. Tahiti, a double volcano, is the largest island in the Societies, comprising roughly two thirds of the Societies' total land area of 1,600 km.

The first human settlement of Tahiti may have occurred as early as 200 BC when settlers from Samoa and/or Tonga moved eastward; this chronology, however, based on dates from the Cook and Marquesas islands, has been disputed by some archaeologists. The earliest acceptable dates hover around AD 600, but because this would include a "long pause" of more than 1500 years between the settlement of Western and Eastern Polynesia, other researchers have argued that the earliest occupation sites have not yet been found. As further work is conducted and radiocarbon chronologies are more accurately determined (especially in places such as the Marquesas) the issue of when settlement actually occurred may be resolved.

Early archaeological research in the Societies began with Kenneth P. Emory in the 1920s and Garanger in the 1960s who primarily studied *marae*, the stone temples commonly found throughout Eastern Polynesia. Unfortunately, early focus on these ancient structures has resulted in a gap in understanding other aspects of prehistory in Tahiti and the rest of the Society Islands, although this been changing in recent years.

Due to this lack of intensive chronological research, only a basic chronology of human settlement has been proposed for the Society Islands, and primarily for the 'Opunohu Valley on Mo'orea. For this valley, Roger Green from the University of Auckland proposed four main phases of occupation: 1) the Pre-Atiro'o Phase (AD ??–1000), in which shifting cultivation occurred on the hillsides which led to heavy erosion; 2) the Atiro'o Phase (AD 1000–1650), in which the first evidence for stone structures appeared along with the development of arboriculture, especially of the Tahitian chestnut; 3) the Marama Phase (AD 1650–1788), which was signaled by the conquest of the area by other chiefs, as well as the construction of elaborate

marae; and 4) the Pomare Phase (AD 1788–1812), a period when European contact led to massive changes in the traditional lifestyles of local inhabitants. Throughout this cultural sequence, Polynesians in Tahiti and the rest of the Societies were becoming increasingly complex socially and economically, with an elaboration of temples that show an increased control by the social elite.

European contact with Tahiti came after the British explorer Samuel Wallis landed on the island in 1767. The hospitality of the local Pomare family toward these and other Europeans fueled the myth of Polynesia as a "paradise" where people lived and loved freely. As Patrick Kirch noted in 2000, "No island society was more influential in forming eighteenth-century European conceptions of Polynesia and the 'noble savage' than 'Otaheite,' purported isle of love and salubrious existence where nature's bounty made work unnecessary."

Throughout the late 18th and 19th centuries, trade and exchange between Tahitians and Europeans grew. One of the most famous trading incidents occurred in 1789 when the H.M.S. *Bounty* arrived in Tahiti to gather breadfruit trees so to feed slaves in the Caribbean. Captain William Bligh was set adrift with other crewmembers after the ship was captured by the Master's Mate Fletcher Christian in the famous "mutiny on the *Bounty*." The mutineers returned to Tahiti where some of them decided to stay; the others, including Christian, escaped to the remote island of Pitcairn with some Tahitian men and women, forming a small colony. After a violent beginning, they settled down; many of the descendents of Pitcairn today are related to the *Bounty*'s mutinous sailors.

TAJ MAHAL

The Taj Mahal stands on the banks of the Yamuna River in the city of Agra, in the northern Indian state of Uttar Pradesh. It is one of the most recognized buildings in the world. The Taj Mahal is actually a complex containing a mausoleum, a mosque, a guesthouse, a large entrance gate, and extensive gardens filled with waterways, pools, and fountains. The monument was constructed in the 17th century under the direction of Shah Jahan at the peak of Mughal power in India.

The Mughal Empire (AD 1526–1707) was a stable unifying force in India for two centuries. Its roots can be traced back to Central Asia. Mughal is the Indian spelling of Mongol. The Mughal style blends balance and harmony with intricate decoration. Mughal influence is still seen throughout India today in architecture, language, customs, and fashion.

Shah Jahan rose to the throne at the peak of the empire's power and glory in 1627 after five years of rebellion against his father. Mughals had no system for determining ascension to the throne, so imperial princes were forced to fight for it. The strongest or smartest would become the next emperor. Shah Jahan immediately ordered the deaths of a brother, nephew, and some cousins to clear away possible rivals. He settled his family into Akbar's Red Fort palace, took control of the empire, and commenced almost 30 years of peaceful rule.

Shah Jahan's favorite wife was Mumtaz Mahal. She was beautiful and very intelligent and would accompany the Shah everywhere as his closest adviser. When she died in 1630 while giving birth to his fourteenth child, Shah Jahan went into deep mourning for two years. In 1632, he ordered the construction of a mausoleum at Agra to house her remains. The entire

project took 22 years to complete with the efforts of 20,000 laborers and craftsmen.

Two supervisors were chosen to oversee the project. Workers came from all areas of the empire, Persia, and Central Asia. A site was selected on a bend of the Yamuna River in sight of the Red Fort. To prepare the site, a deep foundation was set on arches. This base was constructed to protect the mausoleum against flooding during the monsoon season. The base for the tomb was constructed from red sandstone, a common building material of the time. The tomb itself, however, was built of solid white marble, which appears to change color in the light at various times of the day. The marble is covered with intricate inlay of precious and semiprecious stones incorporating three major elements seen in Muslim art: passages from the Qur'an, flowers and plants, and geometric designs. The artisans were so skilled that it is very difficult to see any seams in the marble panels. As you read the passages going up the wall, the letters gradually increase in size so the lettering looks uniform from the floor. The calligraphy inlay was created with onyx. Twenty-eight varieties of precious stones were used for the designs. Materials were brought great distances by elephant, including jade and crystal from China, turquoise from Tibet, sapphire and lapis lazuli from Sri Lanka, and more.

The stone monuments for Shah Jahan and Mumtaz Mahal are in a large central chamber under the dome. A lacy marble screen keeps visitors at a respectful distance. The actual tombs are in a chamber beneath that. The tomb chamber originally had massive silver doors, chandeliers, and precious Persian carpets. The tombs were covered with sheets of pearls. All of the finery here was stripped and carried away by marauding soldiers more than one hundred years later when the empire was in a shambles.

The Taj Mahal is flanked by two matching red sandstone structures. One side is a mosque for guests to pray in, and the other side is a guesthouse for visitors. The garden is divided into four quadrants by waterways representing the four rivers of Paradise. Each quadrant is divided into four, and those again into four, making an ordered, symmetrical grid. The gardens are filled with shade trees and flowers. Fountains and a reflecting pool make a peaceful place for walking. The entrance of the huge front gate perfectly frames the entrance to the tomb. The design of the Taj Mahal both structurally and decoratively expresses joy and happiness; Islamic tombs are not

TAMARINS

Tamarins are one of 16 species of small New World monkeys grouped in two genera: *Leontopithecus* and *Saguinus*. They belong to the subfamily Callitrichinae,

which also includes their smaller counterparts, the marmosets (*Callithrix*, *Cebuella*, and *Mico*) and Goeldi's monkeys (*Callimico*). Callitrichines are the smallest monkeys in the world, with bodies ranging between 20–30 centimeters in length with a tail of 30–40 centimeters. They have thick fur, which makes them look deceptively larger than their actual body size. In addition, many are brightly colored and have distinguishing manes, tufts, and moustaches. Callitrichines are unlike other New World monkeys in several features: they do not have prehensile tails, they lack a third molar (except *Callimico*), and they regularly have twin offspring (except *Callimico*). Callitrichines were once considered the most ancestral New World monkeys because of their small body size and derived claws (instead of nails). However, these traits are more likely derived specializations related to adaptations for insectivore and exudate (gum and sap) feeding rather than signs of primitiveness.

Tamarins are found in the tropical regions of South America and Panama. They are diurnal, arboreal, quadrupedal, and feed on plants, insects, and exudates. Tamarins are unable to gouge holes in tree

bark to stimulate the flow of exudates. Instead, they exploit exudates found at holes previously gnawed by sympatric marmosets or holes made by wind and insects. Tamarins use their derived claws to cling to tree trunks while feeding on saps and gums and for searching for insects hidden in tree bark.

Tamarins exhibit variable social organization and have been found in polygynous, monogamous, and polyandrous groups mostly composed of recently dispersed, unrelated individuals. In polyandrous groups, there is often one breeding adult female and more than one breeding adult male. It is thought that male

tamarins allow other males reproductive access to the female because the survival rate of offspring raised by two fathers is higher than the survival rate of offspring raised by one. Adult males and other group members play an active role in raising the young, which is necessary since female tamarins often give birth to twins. By having group members help carry the infants, females do not expend unnecessary energy transporting them. This also allows females to forage unimpeded. In addition, healthier females are able to produce more offspring at more frequent intervals. In tamarin groups in which there is more than one adult female, the subordinate females' reproductive capabilities are often hormonally suppressed by the dominant female. This means that even though there may be more than one adult female capable of breeding in a tamarin group, usually only the dominant female produces offspring.

At least three species of tamarin are considered critically endangered: the black-faced lion tamarin (*L. caissara*), the black lion tamarin (*L. chrysopygus*), and the golden lion tamarin (*L. rosalia*). The latter is most known for a successful captive breeding program and reintroduction into the forests of Brazil when it was on the brink of extinction.

Taphonomy is the study of processes by which organic remains and traces are incorporated into the fossil record. The term is derived from Greek roots: *taphos*, meaning burial, and *nomos*, meaning law. Taphonomy is the subdiscipline of paleontology and archaeology predominantly concerned with the characteristics and context of fossil remains, in which the challenge of deciphering information from ancient remnants is considerable. The rigors of death, transport, and burial severely modify and degrade organic remains to cause information loss: loss of original chemistry, loss of original size and shape, and loss of biological context. Only rarely do geologic processes stem this loss and preserve the remains of an individual or assemblage as a fossil. By then, the richness and diversity of a living ecosystem has become a few bones or shells scattered along a thin layer of siltstone. By measuring, mapping, and understanding the way dead vertebrate, invertebrate or plant remains behave on this transition from biosphere into lithosphere, taphonomists help clarify natural biases of the fossil record and oppose the entropy of information invoked by death and time.

History

The origins of taphonomy lie in the development of paleontology during the late 15th century, when Leonardo da Vinci recorded concern that marine fossil deposits found at elevations far from the coast could not be explained by the preponderant theory of biblical deluge. Questions about what agents and mechanisms could explain the mortality, assemblage, and preservation of such fossil deposits formed the basis of taphonomical investigation, as it became recognized that a better understanding of these processes could provide more accurate answers about ancient life and environments. Archeology and forensic science were also challenged by postmortem processes to focus, in archaeology's case, on prehistoric hominid reconstructions, and in forensic sciences, to discern the time and cause of death for legal reasons. The fusion of these aspects with concepts of physical biology and sedimentology occurred in 1940 when the Russian paleontologist Efremov coined taphonomy as "the study of the transition (in all its details) of animal remains from the biosphere into the lithosphere."

Process and bias

Taphonomic studies are based upon observing the abundance, distribution, and modification attributes of fossils. Data collection starts with the mapping, measuring, and identification of all elements in context with enclosing sedimentology. The taxa present may be identified and any evidence of sexual and age distributions considered, with a view to later calculating the relative abundance and representation of different species.

The spatial relationships and orientation of fossil elements can be critical to the interpretation of paleohistories. The alignment of elements (or a whole carcass) can demonstrate factors from the time of death or burial such as stream flow direction and rate of deposition. Further information about the taphonomic history may be deduced by combining the spatial data with detailed lithological study. In the case where an accumulation of bones with vertical orientations could derive from a high-energy hydraulic event or be the result of biological factors like trampling around a waterhole, the structure of sedimentary layers surrounding the bones will indicate the correct paleohistory.

Further evidence can be found directly on the fossilized elements, most of which show modification and damage from different stages of their life-and-death cycle. By studying characteristics of the damage, such as shape, size, and position on the element or carcass, the most likely explanation or taphonomic path may be resolved. Pathological and traumatic damage is sustained during life and is evidenced by diseased tissue, natural fractures, and healed bone growth. Postmortem damage may result from many factors including predation, scavenging, trampling, and transport, which may all leave signs upon the hard tissues, such as tooth marks and erosions. Postburial damage is sustained due to the compaction of burial in sediment or diagenetic dissolution, which may leave characteristic fractures.

The correct identification of such fossil evidence can be greatly assisted by studying the taphonomic path of modern organisms. For example, when reasoning why there is a preferential preservation of males over females in Pleistocene deposits of fossil Irish elk, it may be of great help to study the factors affecting seasonal mortality in extant elk herds. Other types of actualistic experiments may include the butchering of mammal carcasses or monitoring the

Source: Photograph courtesy of Mark James Thompson.

agents of decomposition, comparing the effects on fresh organic tissue with those of fossil counterparts. Conclusions must allow for differences when comparing environments across great timespans in order to minimize the degree of bias that will inevitably develop.

Our view of the quality and quantity of biota in ancient environments can also be biased due to organisms having different preservation potential. Mortal processes tend to destroy soft-bodied organisms and preferentially preserve those with hard shells or strong skeletal structures. This causes hard-bodied organisms to be overabundantly represented in the fossil record, skewing our data with which to reconstruct accurate paleoecologies. The effect can apply equally within fauna or marine environments, in which the movement of shell material by waves or currents will affect the eventual composition of the fossil assemblage. Small or thin shells may be abraded away while larger, more robust shell material may be concentrated. Another factor for taphonomists to consider is that only those remains of organisms inhabiting a depositional environment will tend to be buried and fossilized, compared to those from

erosional or nondepositional areas. These sorts of factors explain the paucity of taxa in some fossil assemblages, and why fossils of terrestrial vertebrates are rare compared to marine invertebrates. In extremely rare cases a mass mortality event will capture a census assemblage where all of the contemporaneously living members of a community are preserved together. These exceptional deposits are termed *Fossil-Lagerstätten*, coined from a German mining word meaning *mother lode*. These deposits are treasured for their greater, more complete sample of biota that provides less biased evidence with which to study paleoecologies.

Mortality

Death is an inevitable part of the cycle of physical elements through a biologic host, and the modes of death may be coarsely classified into dying or being killed. Although the actual causes of mortality are many and include death by predation, drowning, dehydration, starvation, and hypothermia, amongst so many others, it remains difficult to ascertain with confidence the cause of death in any long-dead organism from its fossilized remains. Any direct evidence of fatal cause is usually requisite in the soft tissues, which rarely endure into fossilization. Most evidence of attritional mortality is ambiguous. Even in the rare fossils in which a vertebrate forms the stomach contents of another, it is challenging to determine if the consumed organism was killed in the act of predation or was in fact scavenged after an earlier unrelated mortal event. Catastrophic events can be more suggestive by providing an apparent sedimentological record with which to analyze mortal cause. Dinosaurs in Mongolia were fossilized in the act of fighting or still perched upon a nest of eggs, demonstrating how rapid the sand-slides were that entombed them, and thereby showing the likely cause of death to be suffocation.

Biostratinomy

At the instant of death, a host of biological and physical processes will modify and degrade an organism's remains until the potential protection of burial. The study and understanding of these processes and their effects on taphonomic histories is called biostratinomy. The first agent of change is usually necrosis, the process of decomposition and putrefaction.

This removes the soft tissues that normally bind bodily elements together, allowing them to disarticulate. Other agents that can effect disarticulation are predators and scavengers, including ancient man whose tool use during butchering operations created unique marks and fractures on bony elements. Necrolysis and disarticulation also have the effect of exposing a greater amount of the remains to weathering factors such as saturation, desiccation, and temperature changes, as evinced by characteristic surface textures, oxidation, flaking, or fractures. The consumption of remains by predators and scavengers will often result in further disarticulation and scattering, but not the total loss of material. The resulting fecal deposits are termed *coprolites*; these can provide valuable information of dietary behavior, while elements that have been consumed and passed can be deduced from characteristic corrosion of surfaces.

Most organic remains undergo some form of transport between death and incorporation into the fossil record, either by physical or biological processes. Due to the inherent nature of sedimentation, hydrodynamic transport and sorting of remains is often a major agent of dispersal or accumulation. In the case of vertebrates, it is common for the different individual bones, which have different hydrodynamic properties, to be transported different distances from the initial point of death. Plants too are only very rarely preserved in situ with all their different components attached: leaves, stems, trunks, fruit, flowers, and seeds. An organism's remains believed to be in situ are termed *autochthonous*; whereas if the remains have moved they are *allochthonous*. Because allochthonous fossil assemblages require transport, there will usually be evidence of the transport process such as abrasion or an obvious contrasting environment. A vertebrate carcass, bloated with the gases of necrolysis, can float away from the site of death to travel great distances on ocean currents before descending to the sea floor. Fossilized remains of dinosaurs, found wholly within marine sediments, indicate the carcasses were transported over 60 kilometers from their nearest terrestrial habitat. But not all hydraulic agents of transport have the effect of dispersing remains. Rivers can concentrate scattered elements to form rich bone-beds in point bar deposits, and wave action in marine settings may concentrate invertebrate remains to geological proportions.

There can also be active biological agents of accumulation to consider in taphonomic study. Extant

porcupines in Africa have been observed collecting up to thirty-eight bones each year, accumulating them in each lair to gnaw on for minerals and to control the length of ever-growing incisor teeth. This type of taphonomic history may be indicated in an accumulation of fossil bones where flat-bottomed grooves on bones are prevalent.

Diagenesis

As remains are entombed, usually in sediment but sometimes in amber, they become isolated from biostatinomic modifications, but then begin a new stage of different processes acting to modify their original mineralogy and texture even further. This post-burial physical and chemical alteration of remains is termed diagenesis. After deposition, organic tissue is compacted as it is buried beneath successive layers of sediment. Hard tissues will be broken, the resulting fractures combining with those of previous processes to obscure the true taphonomic histories. Compaction also causes plastic deformation that distorts morphological measurements, and in some cases causes misidentification of elements or even taxa.

As the organic tissue and any associated bacteria come into contact with ascending or descending groundwater, the remains become a focal point and catalyst for geochemical reactions of enrichment or dissolution. It is common for the organic tissue to be dissolved away altogether, leaving only casts and molds in the sediment to preserve a shape or outline. Carbonization occurs where the original remains are lost as volatiles, leaving behind a film of mostly carbon that can preserve soft tissue outlines and is a common mode of plant preservation. When the surrounding groundwater contains favorable elements in solution, processes of mineralization may take place. Minerals like phosphate, pyrite, quartz, and calcite may precipitate into the pore spaces and replace the original tissue structures. In exceptionally rare cases, anaerobic bacteria may continue activity for some time after burial, their metabolism releasing gases that initiate rapid precipitation at the microscopic sites of consumption. In this way, soft tissues such as skin and internal organs are preserved as three-dimensional, mineralized replacements.

The mineralizing processes of diagenesis may assist the long-term preservation of the remains by replacing relatively soft bone minerals with those more resistant to crushing and, much later, erosion. From

this aspect, diagenesis and other mortal processes may be seen to provide information of the past rather than destroy it, enabling material to be discovered for the taphonomist to ponder.

TARSIERS

Tarsiers are small arboreal primates (genus *Tarsius*) that inhabit the forests of various islands of the Philippines, where they are active primarily during dawn and dusk. Their common and genus names reflect the fact that this small primate's tarsal (ankle) bones are extremely long, making its "heel" a major component of hind limb elongation. Functionally, tarsal elongation acts as a lever in the tarsier's leaping mode of locomotion. There are at least five recognizable species of *Tarsius*: *T. syrichta*, *T. bancanus*, *T. spectrum*, *T. pumilus*, and *T. diana*. Solitariness among males and females is the most consistently documented social behavior.

Tarsius is unique in many ways compared to other extant primates. It is the only primate with reptilian-like scales, which are located around

its nipples and on its tail (which bears a tuft of hair only at its tip). It is also the only primate whose tail is longer than its body and whose eyeball is larger than its brain. It has conical eyeballs that do not move in their sockets, however it can rotate its head 180 degrees in either direction. The tarsier grows sinus hairs externally on its nose and has interdigitating, sensory hairs around its upper and lower lips (forming an "oral organ"). It has a grooming claw on its third pedal digit. It is also the only primate that develops hemochorial placentation in the environment of a bicornuate uterus, and that begins amniogenesis via cavitation but then converts the process to folding. The tarsier is totally proteinivorous, eating prey larger than itself, including fish, birds, lizards, and poisonous, neurotoxic snakes. Whether as a result of becoming unique or remaining primitive compared to other primates, the tarsier bears a well-developed anterior cusp (paraconid) on all three of its lower molars that lies distinctly apart from the next cusp behind (metaconid). Its upper anterior teeth are caniniform and those behind increasingly premolariform; the lower anterior teeth resemble the lateral teeth of toothcombed primates, with the teeth behind becoming increasingly premolariform. Furthermore, its chromosome number is the greatest among primates ($2N = 80$).

Tarsiers have for the longest time been grouped with primates of Madagascar, lorises, and bushbabies in the suborder *Prosimii*. One compelling reason is that they all uniquely possess a grooming claw on the second pedal digit. The morphological counterpart to

Source: © iStockphoto/Ronald Fernandez.

the lateral tooth of the uniquely prosimian toothcomb complements this hypothesis. Dental features link *Tarsius* with the loris group.

In 1918, Pocock grouped *Tarsius* and anthropoids in the suborder *Haplorhini* because they all supposedly have laterally continuous (not slit) nostrils. The remaining prosimians were relegated to *Strepsirhini*. Pocock was incorrect about *Tarsius*, but Hill kept *Haplorhini* alive by confusing “single nostril” with “single upper lip,” a feature that does not, however, correctly characterize all New World monkeys (making *Tarsius* and catarrhines the only primates with a smoothly continuous upper lip). Various questionable features have been invoked in support of *Haplorhini*, for example, hemochorial placentation (but cetaceans and various bats and rodents, not *Tarsius*, approach the anthropoid condition) and partial postorbital closure (which develops differently and involves different bones in *Tarsius* versus anthropoids). The absence of a retinal fovea and a rhinarium do, however, support this hypothesis.

The first evidence of human habitation on Tasmania dates from around 23,000–25,000 years ago, when the Bass Strait was actually a land bridge and allowed for easy passage between the mainland and Tasmania. Then, between 8,000–12,000 years ago, with the warming of the Earth, the Strait flooded, leaving the small population stranded for the longest period of human isolation ever.

These aboriginal Tasmanians were hunter-gatherers who ate marsupials such as wombats and kangaroos,

seafood such as crayfish and crab, and plant foods such as sea kelp, roots, berries, and fungi. Their political organization was akin to many other food collecting societies in that homestead groups of between two and eleven were joined together through both kinship and geography into acephalous bands of 40 or 50 people. Bands were the primary landholding units, not landowning as there was no private property recognized, while tribes were the largest political units. Contemporary aboriginal organizations say that nine tribes existed prior to European contact. While some publications speak of 35 coastal and 22 inland “tribes,” this is most likely a misuse of the word for what anthropologists generally call bands.

Despite their relatively simple technology, Tasmanian aborigines did not live in a “state of nature.” They transformed their habitat through the use of controlled burns to clear the land for easier travel, flush out animals, and encourage the growth of new plant life. They also created tools, nets, and baskets and other containers from bone, wood, stone, woven grasses, sinew, seaweed, and bark. Small boats were also constructed out of bark and grasses, to travel to offshore islands in the summer months for hunting seal and muttonbirds and gathering other seasonal foods.

Tasmania’s cold, wet climate necessitated both shelter and some protection for the naked body. There were two basic designs for shelter: bark, lean-to windbreaks and dome-shaped huts thatched with grass or bark and lined with feathers or fur. This latter form dominated in Tasmania’s cold western area and were lived in year-round, while the temporary windbreaks sufficed in the warmer areas of the east. Despite Tasmania’s weather, most people actually wore very little clothing. Women did don cloaks made of kangaroo skins, as did men at the coldest times, but children and many adults protected themselves largely by rubbing a mixture of fat, ochre, and charcoal onto their skin. In addition to this adornment, adults also practiced cicatrice, or ritual scarification, and wore necklaces of fur, shell, or other materials.

Tasmanian aborigines’ religion had many features in common with those on the mainland. They believed in spirits, had totemic animals and plants, and observed their associated taboos. They also cremated their dead, avoided speaking of them afterward, and had a strong belief in the afterlife. The only existing examples of Tasmanian visual art are geometric petroglyphs of circles, lines, and dots seen today on

the west coast, which may tell creation myths and other dreamtime stories. Unfortunately, few language features—other than several songs, place names, and a few word lists—were recorded from the five related dialects that were spoken on Tasmania prior to European settlement.

The first person of European descent to land on Tasmania was Dutch explorer Abel Tasman, who arrived in 1642 but did not see any of the island's inhabitants. This event didn't recur for another 130 years; in 1772 Nicholas Marion du Fresne, a French explorer, met a large number of aborigines at what is now called Marion Bay. Later, many more European explorers, including Cook, d'Entrecasteaux, and Baudin, all made brief landings on the island and enjoyed relatively friendly relations with the natives. Unfortunately, this changed in 1803 when European settlers arrived on Tasmania, bringing with them superior weapons, new diseases, and ideas about both private ownership of land and the evolution of human societies that had devastating effects on the indigenous population. For example, in November, 1828, Europeans were given permission to kill any indigenous person on sight when martial law was declared on the island. In the end, this devastation was so great that by the 1830 census, only 350 aborigines were recorded and by the late 19th century, most Europeans believed that the last Tasmanian aborigine, Truganini, died in May, 1876.

Fortunately, the mythology of Truganini as the last Tasmanian was just that, mythology, for in the 2001 census, 15,773 Tasmanians identified themselves as being indigenous, far more than the estimated 1,500–7,000 who lived on the island before European settlement. This transformation has been fueled on three fronts. First, the recognition of aboriginality by those of European descent has been delinked from strict racial definitions to include the descendants of those aborigines who were transported to the Furneaux Islands in the 1830s, many of whom married or at least had children with the small European sealing community that had taken up residence on some of the larger islands. Many of these people moved back to Tasmania between the 1940s and 1970s, for economic reasons. Second, political developments among aborigines themselves have encouraged more people to recognize their own indigenous origins. Third, some aboriginal people from the mainland and Bass Strait and Torres Strait islands have moved to Tasmania in the past decades.

The priority for many people who consider themselves today to be aboriginal Tasmanian is cultural recovery. Toward this end, aboriginal child care centers were established in both Hobart and Launceston in the 1980s. Numerous aboriginal community events also take place each year in cities, towns, and at aboriginal sites all over Tasmania. The other priority has been the physical recovery of ancestral remains from museums all over the world, toward which the state of Tasmania has been helpful in passing a law requiring all such samples be returned. As a result, in February, 2002, the British College of Surgeons returned samples of Truganini's skin and hair, along with the bones of other indigenous Tasmanians that they had held since the 1870s. Numerous other scientific institutions both in and outside of Australia have done likewise since the 1970s.

TAX, SOL (1907–1995)

Dedicating himself to the dual goals of “action anthropology” and the internationalization of anthropology, Sol Tax was instrumental in changing anthropological practice and pioneering new forums for anthropological debate. Although he published relatively little over the course of his career, Tax made significant contributions in three theoretical areas of anthropological research: acculturation, capitalism in small-scale societies, and cultural identity.

With regard to action anthropology, Tax's activist-oriented approach to anthropological practice led the way to the contemporary approaches to applied anthropology. During the 1940s, Tax opposed what

was then considered applied anthropology because it was based in an ideology of modernization that disregarded the culture of those being aided. In order to disassociate himself from applied anthropology of the time, he conceptualized action anthropology as a practice in which anthropologists not only learn but, of equal importance, aim to help. Such ethnographic projects must consider the opinions, needs, and critiques of those who are the subjects of study and aid. His contributions are recognized by the Society of Applied Anthropology, which awards the Sol Tax Distinguished Service Award to anthropologists who have demonstrated long-term commitments to applied approaches, communication among the subdisciplines, ethical practices of research, and editing anthropological journals.

As director of the Fox Indian Project, Iowa from 1938 to 1962 and as an ethnologist working for the Carnegie Institution in Guatemala from 1934 to 1946, Tax participated in substantial ethnographic projects, in which his action anthropological approach was evident. With the Fox project his position on action anthropology congealed. Reacting against the acculturation models of post-World War II anthropology, Tax took the position that then current models—preserving traditions and acculturation into the dominant society—were theoretically inadequate and failed to serve the best interests of the Fox. In contrast, Tax argued that the Fox and other American Indians were and continued to be active agents in the processes of change. The culmination of the Fox project and his position on action anthropology came with the pan-Indian “American Indian Chicago Conference” in 1961, which focused on the future, not on their past and the maintenance of tradition.

Tax’s research in Guatemala proved to be the most fruitful theoretically. For more than 50 years, his book, *Penny Capitalism*, has generated debates within anthropology as well as within other disciplines about the effects of capitalism on and the economic rationality of members of small-scale societies. Furthermore, it preceded Chaynovian-inspired analyses of household peasant economics by nearly 15 years. Parallel to the economic debates are those related to cultural and ethnic identity. Under his influence, Mesoamericans ceased to be identified as members of tribes, and he recognized that identity was oriented first around community, not language. More importantly, his discussions of Mesoamerican indigenous identity anticipated postmodern theories of difference

and power relations as essential components to cultural identity.

From organizing international symposia to translating many of the ethnographic monographs associated with the Carnegie project into Spanish, Tax’s most significant contribution to the internationalization of anthropology was the founding of the journal *Current Anthropology* in 1959 with the support of the Wenner-Gren Foundation for Anthropological Research. Since its inception, with Tax at its helm for the first 15 years, the journal has been dedicated to publishing anthropological research from all subdisciplines submitted by international scholars and reviewed by an international board.

Technics can be a tool extending human body parts and senses or a combined physical system (man-tool, man-machine, man-natural process) created by a culture and utilizing human powers and external natural powers, structures, and systems for human cultural purposes. It is not important whether these systems and powers are predominantly animate or inanimate, natural or artificial, located inside or outside of humans. Technics may be human work with bare hands or with a tool, a factory production line, soil cultivation with a tractor or with animal power, corn

Source: Courtesy of the Library of Congress.

growing, bread baking, or wine fermentation. There is one phenomenon differentiating technics from nature: the relevant structures and powers must establish a purposeful process that doesn't work primarily for nature but for humans.

The term "technics" is usually understood objectively, with the emphasis placed upon the artificial element of the total technical system. It usually represents the "technical phenotype," that is, the means of the technical operation: a tool, a machine, or an automatic system. The term "technology," on the other hand, is understood as a process, as the functioning and operation of the technical systems.

Technics is a part of the human, antinatural culture and is rationally understandable only within this culture. Yet we must distinguish between two historical levels of technical development and between two basic development lines of technics: *biotic* and *abiotic*.

Hunting and gathering was the first stage of biotic technics development; its second stage, the Neolithic Revolution, was the first great technical revolution. The Neolithic period witnessed the arrival of almost all cultural plants and domestic animals. Basic procedures of food "manufacturing" and processing were also discovered during this time. Even the third stage of biotic technics development—the modern biotechnologies, cloning, and genetic manipulation—will hardly be able to surpass the Neolithic Revolution. Neolithic biotic technics, as a cultural channeling of a

possibly multifunctional live system, was in harmony with the similarly antinatural abiotic technics: it utilized the activities and characteristics of live systems but it didn't interfere with their genetic information; it didn't distort the natural biospheric information.

The abiotic technics production line, which is usually connected with the idea of technics itself, can be schematically described by the following terms: *tool-machine-automation*. This line developed in harmony with biotic technics up to the Industrial Revolution, that is, in harmony with the human skills and procedures utilizing the processes transforming live organisms.

This difference between the two lines of technical development presents not only the hidden antinatural character of all technics but also the environmental

advantages of the currently neglected biotic technics. Naturally, abiotic technics is more aggressive environmentally. Even though its energetic and functional bases were originally based in humans (humans activated and controlled tools), the original human functions in the instrumental anthropotechnical system (especially those energetic and kinetic ones) were transferred to the technical system from the beginning of mechanization. And this technical system doesn't retrieve its energy from renewable resources but from nonrenewable fossil biomass.

The energetically much more thrifty biotic technics is mostly represented by live systems even today: microorganisms, cultural plants, domestic animals. Biotic technics remains, therefore, connected to the weakly integrating renewable energy of the Sun, even though it is forced to operate on behalf of man and culture.

The first stage of the historical development of abiotic technics—instrumentalization—was characterized by slow improvements and differentiation in tools. It developed in harmony with biotic technics for millennia. Classic workmanship utilized natural human skills; it developed both the physical and intellectual characteristics of human beings, and its destructive effects on humans were negligible. Then, in an attempt to increase work productivity and utilize the power of cooperation, workmanship was divided into suboperations comparable with the later

machine operations. This was the beginning of factories where human beings worked instead of machines.

The second stage of abiotic technics development—mechanization—was disseminated by the Industrial Revolution. Mechanical technics, which replaced artisans, brought the huge productive forces of science into the manufacturing process. Nevertheless, along with the increased productivity of human work, machines started a technological oppression of humans. From the very beginning, this technics tended to establish large machinery systems—factories. This was the basis for a strongly integrated global technosphere. Two large abiotic subsystems based on fossil fuels and spanning the whole planet appeared in the 20th century: (1) a predominantly stationary machinery subsystem (the power plant, electric power distribution networks, and other stationary mechanical technical devices), and (2) a predominantly mobile machinery subsystem (oil refineries, a worldwide network of oil product pumping stations, various vehicles, etc.).

The third stage of the abiotic productive technics development—automation, characterized by the establishment of fully artificial, technical systems—has disposed of the technological oppression of man but has narrowed the possible exercise of human labor in the labor market. Automated technics originates not only as a result of a high degree of scientific knowledge development. It also originates because natural biotic evolution has not utilized all the possible substance configurations in the environment of the Earth. The original, natural ecosystems, which were designated for all living things, were disturbed by technics, occupied, and transformed into an environment designated exclusively for humans.

The current postindustrial phase of abiotic technical creativity is based on an arrogant approach to nature. There is almost no respect for the values, integrity, and requirements of the natural evolution of the biosphere. Even though traditional biotic technologies are still used, and even though there are new technologies that are less aggressive toward nature, preserve energy, and produce minimum or no waste, the general character of the human approach to nature remains unchanged. This is more than just the dominance of abiotic technology; this is the dominance of the abiotic model for creating and satisfying human needs. The establishment of environmentally friendly manufacturing processes is up against environmentally reckless consumption. The technics-saturated human

lifestyle also includes environmentally destructive consumer technics: private cars, household devices, hobby equipment, computers, TV sets, mobile phones, and so on.

The environmentally significant term *technosphere* describes a transnational system of functioning, reproduction, and evolution of technics. This spontaneously expanding and culturally determined system includes not only abiotic technics; it also includes the older and environmentally less aggressive biotic technics. Nevertheless, abiotic technics is dominant in the current technosphere. Its expansion, enlarging the cultural space, proceeds along many axes: vertically, horizontally, and transversally. New technical forms automatically occupy free social-cultural niches similar to the way plant and animal populations occupied their ecological niches.

Even though the evolution of technics and the technosphere is qualitatively different from the evolution of live systems and the biosphere, both fields are connected by many analogies and isomorphisms. For example, both evolutions need a comparatively free substance and energy; both need their own, internal information. A significant input of energy is able to include even rather large inanimate structures in the artificial technical systems, which are then capable of purposeful operation, specific cultural reproduction, and evolution.

The genetic information of technics, which has become a part of the social-spiritual culture, is created neither by an average human individual nor by the current world culture. It is created by a highly specialized element of the workforce in the technically most developed countries—by the technical intelligence. And this element can also complement it, change it, and develop it in the direction of the desirable technics. However, abiotic as well as biotic technics have coexisted with humanity from the very beginning; they have helped humans survive and to a certain extent they have been established by nature itself: by the position of humans in evolution, by humans' special biological equipment, and by our need to defend our environmental niche even under undesirable natural conditions. Let's hope that the precultural natural-biological dependence of humans upon technics will not just reproduce itself again and again but will eventually force us to establish a sustainable form of the planetary technosphere.

TEILHARD DE CHARDIN, PIERRE
 (1881–1955)

Are science and theology reconcilable in terms of evolution? As both an eminent geopaleontologist and cosmic mystic, Pierre Teilhard de Chardin presented a dynamic worldview. He argued that the human species does occupy a special place within a spiritual universe, and that humankind is evolving toward an Omega Point as the end goal of converging and involuting consciousness on this planet.

With his steadfast commitment to evidence of pervasive evolution, Teilhard, as natural scientist and Jesuit priest, became a very controversial figure within the Roman Catholic Church during the first half of the 20th century. Because of his bold interpretation of the human species within earth history and this cosmos, he was silenced by his religious superiors for taking an evolutionary stance at a time when this scientific theory was a serious threat to an entrenched orthodox theology. Going beyond Charles Darwin, Teilhard even maintained that evolution discloses the meaning, purpose, direction, and destiny of the human species within life, nature, and this universe.

As a geopaleontologist, Teilhard was very familiar with the rock and fossil evidence that substantiates evolution. As a Jesuit priest, he was acutely aware of the need for a meta-Christianity that would contribute to the survival and fulfillment of humankind on this planet, in terms of both science and faith. Sensitive to the existential predicament of the human species, with its awareness of endless space and certain death, Teilhard as visionary and futurist ultimately grounded his personal interpretation of evolution in process philosophy, natural theology, and cosmic mysticism that support panentheism (defined as belief that God and the World are in a creative relationship of progressive evolution toward a future synthesis in terms of the collective spirit of humankind).

Galileo Galilei endured house arrest and humiliation as a result of his claiming that the earth does in fact move through the universe, a scientific discovery that the aged astronomer was coerced into recanting by his dogmatic persecutor, Pope Urban VIII (formally Cardinal Maffeo Barberini), under the intolerant Jesuit inquisitor, Cardinal Robert Bellarmine.

As a direct result of the conservative standpoint taken by his religious superiors, Teilhard suffered both alienation and discouragement because he claimed that species (including the human animal) evolve throughout geological time, or else they become extinct; his daring evolutionism attacked fixity, essentialism, and biblical fundamentalism.

Discovering Evolution

As a child, Teilhard showed an interest in both natural science and religious mysticism. Sensitive to his beautiful Auvergne surroundings in France, and particularly drawn to the study of rocks, he found delight in a plowshare which he supposed was an enduring object, free from change and imperfection; however, after a storm, the youth discovered that his “genie of iron” had rusted. Later, Teilhard recounted how he threw himself on the ground and cried with the bitterness tears of his life. As a result of this devastating experience, the boy vowed seek his “one essential thing” beyond this imperfect world of matter and corruption. To be “most perfect,” as he put it, Teilhard entered the Jesuit society at the age of seventeen in order to serve God. At the same time, he intensified his interest in geology on the channel island of Jersey. Throughout his entire life, the scientist-priest would never abandon his love for science, concern about human evolution, and devotion to mystical theology—especially eschatology.

In 1905, as part of his Jesuit training, Teilhard found himself teaching at the Holy Family College in Cairo, Egypt. This three-year experience offered him the unique opportunity to do research in both geology and paleontology, expanding his knowledge of earth history. It also exposed him to a rich multiplicity of cultures, both past and present, that surely jarred him from European ethnocentrism. Following this teaching obligation, he then finished his theology studies at Hastings in England.

During his stay in England Teilhard read Henri Bergson's new, major book, *Creative Evolution*. This metaphysical work had an enormous influence on the

scientist-priest, since it resulted in his lifelong commitment to evolution. It is worth emphasizing that it was not Darwin's publications, but rather Bergson's interpretation of evolution that convinced Teilhard that species, including the human animal, are mutable throughout organic history.

While on one of his field trips, Teilhard unfortunately became involved in the discovery of the controversial Piltdown skull, which was later determined to be a fraud. Although he had questioned the validity of this fossil evidence from the very beginning, one positive result of his involvement was that the young geologist and open-minded seminarian now became particularly interested in paleoanthropology as the science of fossil hominids.

After his stay in England, Teilhard returned to France where, during World War I, he was a stretcher bearer at the front lines. Remarkably, he emerged from his horrific experiences in the war trenches even more optimistic that evolution had been preparing the Earth for a new direction and final goal in terms of the spiritualization of the human layer of this planet. In fact, during the global war, Teilhard had several mystical experiences which he recorded for posterity. It was his emerging mysticism that would eventually allow him to reconcile science and theology within an evolutionary vision of the human future that was grounded in a spiritual reality.

In 1923, as a result of an invitation, Teilhard next found himself as a geologist participating in a scientific expedition into Inner Mongolia. A year in China gave the Jesuit a splendid opportunity to begin his career as a specialist in Chinese geology. It was during this time, while in the Ordos Desert, that Teilhard essayed "The Mass on the World," a mystical account of his offering up of the entire world as Eucharist to a Supreme Being as the creator, sustainer, and ultimate destiny of an evolving universe. He expressed his dynamic Christology by viewing this planet as a part of an ongoing spiritual evolution, and continued to devote his life to synthesizing science and theology.

Upon returning to France, Teilhard ran into serious problems with the Roman Catholic Church because of his unorthodox beliefs. In Paris, he began giving public lectures on and teaching about evolution. This Jesuit priest was even bold enough to offer a personal interpretation of Original Sin in terms of cosmic evolution and the emergence of the human species in a dynamic but imperfect (unfinished)

Source: © Bettmann/CORBIS.

universe; he saw this cosmos as a cosmogenesis moving from chaos and evil toward order and perfection.

When a copy of Teilhard's controversial essay fell into the hands of some of his superiors, he was censored by the Church: he could no longer teach or publish his own theological and philosophical views, and he was even exiled from France by the Jesuit order. Teilhard found himself back in China. There he wrote his first book, *The Divine Milieu*, a spiritual essay on the activities and passivities of the human being; Teilhard's unorthodox book was denied publication.

Fortuitously, Teilhard next found himself a member of the Cenozoic Laboratory at the Peking Union Medical College. Beginning in 1928, geologists and paleontologists excavated the sedimentary layers in the Western Hills near Zhoukoudian. At this site, the scientists discovered the so-called Peking man (*Sinanthropus pekinensis*), a fossil hominid dating back at least 350,000 years but now relegated to the *Homo erectus* phase of human evolution. Teilhard became world-known as a result of his popularizations of the

Sinanthropus discovery, while he himself made major contributions to the geology of this site.

The Phenomenon of Man

Attempting to bring his scientific knowledge and religious commitments together, Teilhard began writing a synthesis of facts and beliefs aimed to demonstrate the special place held by the human species in a dynamic universe. Teilhard completed his major work, *The Phenomenon of Man* around 1940; in it, Teilhard steadfastly committed himself to the concept of organic

evolution, but his work was again denied publication by the Vatican.

Teilhard argued that the evolving universe is a cosmogenesis. Essentially, the unity of this universe is grounded not in matter or energy but in spirit (the within-of-things or radial energy); thereby he gives priority to dynamic spirit rather than to atomic matter (the without-of-things or tangential energy). Moreover, Teilhard was a vitalist who saw the personalizing and spiritualizing cosmos as a product of an inner driving force manifesting itself from material atoms, through life forms, to reflective beings. He discerned a direction in the sweeping epic of this evolving universe, particularly with the emergence of humankind. However, his alleged cosmology is merely a planetology, since the scientist-priest focused his attention on this earth without any serious consideration of the billions of stars and, no doubt, countless planets that exist in those billions of galaxies.

Of primary significance, Teilhard argued that the order in nature (as he saw it) reveals a pre-established plan as a result of a divine Designer, who is the transcendent God as the Center of creation or Person of persons; the direction in evolution is a result of the process law of complexity-consciousness. Teilhard was deeply interested in and concerned about the infinitely complex entity that would emerge in

the distant future as the result of a spiritual synthesis, rather than occupying himself with the infinitely great and the infinitely small objects now in this universe.

For Teilhard, this cosmic law of increasing complexity and consciousness manifests itself from the inorganic atoms through organic species to the human person itself; or, this process law has resulted in the appearance of matter, then life, and finally thought. Evolution is the result of “directed chance” taking place on the finite sphericity of our Earth. Teilhard emphasized that evolution is converging and involuting around this globe: first through geogenesis,

then through biogenesis, and now through noogenesis. The result is a geosphere surrounded by a biosphere, and now an emerging noosphere (or layer of human thought and its products) is enveloping the biosphere and geosphere. For this Jesuit priest, noogenesis is essentially a planetary and mystical Christogenesis.

The idea of a developing noosphere was also explored in the writings of the Russian scientist Vladimir I. Vernadsky (1863–1945). Very similar to Teilhard's comprehensive and dynamic orientation, Vernadsky presented a holistic view of life on earth in his major 1926 work, *The Biosphere*.

Teilhard stressed that the process of evolution has not been a continuum: From time to time, evolution has crossed critical thresholds, resulting in the uniqueness of both life over matter and then thought over life. A person represents an incredible concentration of consciousness or spirit, resulting in the immortality of the human soul. Consequently, the Jesuit priest claimed that the human being is ontologically separated from the four great apes (orangutan, gorilla, chimpanzee, and bonobo).

For Teilhard, the ongoing spiritual development of our own species is converging and involuting toward an Omega Point as the end-goal or divine destiny of human evolution on this planet. His theism maintains that God-Omega is one, personal, actual, and transcendent. In the future, God-Omega and the Omega Point will unite, forming a mystical synthesis beyond space and time.

After *The Phenomenon of Man* was denied publication, Teilhard wrote *Man's Place in Nature: The Human Zoological Group* (1950). This work is a more scientific statement of his interpretation of evolution. Unfortunately, the publication of Teilhard's third book was also denied along with his request to teach in Paris.

While living in New York City, Teilhard twice had the opportunity to visit the fossil hominid sites in South Africa. On Easter Sunday, April 10, 1955, Teilhard died of a sudden stroke in New York City. He was buried at Saint Andrew's on the Hudson, far removed from France. By the fall of that year, the first edition of *The Phenomenon of Man* was published in its author's native language.

Teilhard was committed to science, evolution, and optimism despite his daring speculations and mystical orientation. Teilhard introduced into modern theology the concept of organic evolution at a time when this scientific theory was rejected by many who saw it as a

threat. Unfortunately, in trying to reconcile science and theology, the Jesuit priest pleased no intellectual community.

Teilhard was an extraordinary human being of intelligence, sensitivity, and integrity. He experienced both the agony and ecstasy of time and change. His optimistic commitment to cosmic evolution flourished while he served on the blood-stained battlefield of a war-torn humanity, researched among the rocks and fossils of a remote past, and reflected in the deepest recesses of his profound soul on the meaning and purpose of human existence. As such, Teilhard himself exemplifies both the phenomenon of man and the ongoing quest for truth and wisdom in terms of a comprehensive anthropology.

Teleology (from Greek words *telos*, “end,” and *logos*, “reason, discourse”) is the study of processes in nature

as they are driven by their ends, goals, and purposes. This is diametrically opposed to a mechanistic explanation based only on cause–effect sequences in time series.

Teleological thinking was natural for mythical, anthropomorphic explanations of nature. A tradition of nonmythical teleological explanation starts with Aristotle's concept of *causa finalis*, thanks to his extraordinary influence on natural sciences in the Middle Ages, although teleological concepts of nature can be found in pre-Socratic philosophers and Plato's dialogues. Aristotle included the end as an additional and the most important cause of all natural processes. It presuppose in general that a final state of affairs in future explains or predetermines the movement from previous states to final ones.

Teleology was never too far from theology. Theologians in the Middle Ages identified Aristotelian ends and goals in the universe with purposes and intentions—and those with God's will. The Aristotelian concept of *causa finalis*, after being hybridized with Plato's concept of eternal Forms and cosmic Demiurge, started to be a common explanation of a complex design of living beings, their functionality, and their goal-oriented behavior. Argument from design became one of the most important theological arguments for the existence of God. This argument turned out to be even more important with the rise of modern science in the 16th and 17th centuries, when the Aristotelian concept of *causa finalis* was expelled from nonliving nature.

Modern study of Aristotle's philosophy revealed that his concept of teleology traditionally has been misinterpreted. In contrast with general belief, Aristotle did not think that the natural motions and changes of nonliving objects achieved a goal in the same way that developing organisms do. Natural processes of non-living objects, like stones falling down to the center of the Earth, are not (in Aristotle's words) “for the sake of” anything, in contrast to organismal development which is, in fact, for the sake of a mature individual.

Specific philosophical attempts to reconcile the cause–effect mechanistics of Newtonian physics (*nexus effectivus*) with obvious teleological causality (*nexus finalis*) present in living beings were made by Kant (1724–1804) in his *Critique of Judgment*. Kant saw a principal difference between man-made artifacts on one hand and organisms on the other hand, similar to Aristotle. In artificial things, like a clock, all

parts are put together to act as an integral whole; each part exists for the other parts, but not thanks to them, as in living beings. A constitutive force of the clock is outside of the clock, in a human being who is able to act in accord with the idea of the whole. As he pointed out, one cogwheel does not create another one and clocks do not create other clocks; they are not able to replace missing parts by themselves, nor are they able to repair themselves.

It is important to keep in mind that Kant's reasoning on finality was done within the framework of his transcendental philosophy, from which it follows that teleology is a methodological approach rather than an ontological doctrine. We not only can (despite the mechanical cause–effect causality of physics) but we must think of organisms as directed by their own natural goals, and we have to keep in mind that these goals are not analogous to human intentions (“purposiveness without purpose”). They are domain-specific principles (*principia domestica*) of natural science. This is why Kant is so critical of introducing the concept of God to natural science in order to explain teleology in nature, and then later to use natural teleology as an argument for God's existence.

Kant hoped that someday a scientist like Newton would be born who was able to explain even very simple teleological phenomena, like the production of a stem of grass, from natural laws without any need to use the idea of an intentional purpose. His kind of scientist appeared a half century later, and his name was Charles Darwin. Darwin, in his work *The Origin of Species*, came up with a radically new scientific explanation of teleological phenomena in the living world. According to his theory, functional designs and behaviors of organisms are not products of a divine designer, as suggested by the British theologian William Paley in his *Natural Theology* (1802), but adaptations to environment, outcomes of spontaneous evolutionary process based on a combination of genetic changes and natural selection. Both genetic changes and natural selection are, in principle, not goal-oriented natural mechanisms. Genetic changes are random with respect to the direction of adaptation; they do not respond to the needs of the organism for better adaptation (at the time, neo-Lamarckian inheritance of acquired characteristics and directed mutations were not confirmed). Although many evolutionary histories seem to be goal-directed lineages (for example, the evolution of the horse), evolutionary mechanisms are not

providential—neither mutations nor natural selection has a purpose or goal.

The impersonal, nonpurposive, mechanistic nature of Darwinian evolutionary theory has been under strong criticism since it was formulated by Darwin in the middle of the 19th century, first by various so-called vitalists in the late 19th century and early 20th century who tried to understand the teleologic character of individual development. They refused to reduce life to physico-chemical mechanisms, and they argued for life-specific principles. One of the most influential was German embryologist and philosopher Hans Driesch (1967–1941), with his neo-Aristotelian concept of entelechy. According to him, entelechy is an acting force in the embryo working towards developmental ends. Another example is French philosopher Henri Bergson (1859–1941) and his concept of a mystical live force, *élan vital*.

Following the rapid rise in the second half of the 20th century of modern biology based on biochemistry, and later on a molecular approach, almost all biologists rejected the concept of a natural force specific only to living things that does not obey physical and chemical laws. On the other hand, in nonscientific circles, opposition to the Darwinian explanation of life's complexity remains and recently reappeared with the Intelligent Design movement. The main claim the movement is that it follows from empirical evidence itself that Darwinism is not a correct and scientific theory because it is not able to give a fully satisfactory explanation of the adaptive complexity of life. Therefore, it is necessary to suggest the existence of an intelligent designer—a new, not-yet-known, goal-oriented natural force—as a scientific alternative to Darwinism. However, the vast majority of biologists regard the Intelligent Design concept as pseudoscience.

In the classification of architecture, the temple falls into the devotional class, that is, a building constructed as a place of worship. The ancient Indians, Egyptians, Sumerians, Greeks, and Romans all built beautiful temples, which are marked by their own individual characteristics. Temples in some form must have originated as soon as image worship came into vogue, for a temple is the “house of God.” In ancient Indian literature, temples are referred to as *Devalaya* or *Devakala*, meaning the house of gods. The earliest temples, therefore, were modeled after residential buildings.

The Brahmanical conception of a temple, however, is somewhat abstruse. It envisages the temple as the visible outer body of the invisible deity, a visible image of which is installed in it as a symbol of the invisible spirit that pervades all nature, that is, God himself, thus enhancing the status of the temple from the seat of the divine to the divine itself. Since the temple is considered the outer body of the deity, its various parts are given names that correspond to parts of the human body and are likewise decorated with architectural designs. For example, the outer face of a temple with a lavish display of ornamentation is the visible representation of the deity itself.

At the height of its architectural development, the Indian temple was the spiritual centre from which religious and social life was regulated. In addition, there is ample evidence of secular art in the temple architecture. The art on the temple walls and the terracotta panels witness the contemporary socio-economic conditions of the people, thus supplying material for social history too. The *Aryan*, popularly known as the north Indian and *Dravida*, or the south Indian, are the two basic schools of Indian temple architecture accepted since the Vedic times. A temple is indicated as a *Prasad* in the north Indian and as a *Vimana* or *Harmya* in the south Indian school. *Mandir*, the most

Source: © iStockphoto/Karen Grieve.

commonly used word nowadays, meaning a house made of stones, is altogether absent in the earliest known texts and inscriptions. Modern Indian writers recognize three styles of temple architecture: the *Dravida*, the *Nagra*, and the *Vesara*. The Indo-Aryan had no temples. The first small Brahmanic shrines made their appearance in the Gupta period (AD 350–650). Foundations of a single Vishnu temple (Hindu) of the second century BC, however, have been found at Besnagar in Madhya Pradesh. Gupta temples were simple and small with a small cella and carved doorways. South India is the true cradle of Hindu temple architecture. The Hindu temples vary regionally but generally consist of a towering shrine, central cella, and a columned hall surrounded by an elaborate wall. The Buddhists built cave temples, of which Ajanta is one of the most exclusive. There are more than 1,200 rock cut Buddhist temples in different

parts of India. The medieval Jain temples are amazingly beautiful, built on remote and secluded mountain-tops and made of white marble, shining against the blue sky; the most remarkable ones are found at Girnar, Palithana, and Mt. Abu.

In 3500 BC, the cities of Sumer were dominated by huge temples with hieroglyphs on the walls. Later, there appeared sculptures and figurines showing gods, priests, kings, soldiers, slaves, and animals. These were built on hills or mounds in the shape of a pyramid, with steps leading to the top where next to the low temple building stood a very tall tower where God was supposed to live. These mounds made of earth and the temples and towers on top of them were called *ziggurats*. Sumerian temples made an essential contribution to large-scale farming by synchronizing agricultural operations. They owned vast estates and employed their own establishments of slaves, controlled the farm lands, received taxes, and operated as markets and banks. The city-states were, in fact, temple-states that belonged to local gods. Temples in Sumer had many roles—religious, social, and economical. In Babylon there were

two great temple areas. The temple of Marduk, the patron god of Babylon, is the best-known temple, besides nearly 400 smaller altars and 1,000 shrines. Ancient Egypt had two types of temples, the morgue temples for the dead rulers (for example, the temple of Queen Hat-Shepsut in Thebes) and divine temples that held images of gods. The divine temples had a typical architecture—avenues of sphinxes led to the temple flanked by two obelisks that represented the rays of the sun. The temple entrance was constructed with two huge towers called pylons slanted inward and a courtyard leading to a huge hall called a hypostyle hall. At the center was a shrine for the divine image. The Egyptian temples had flat roofs with columns inside. The temple of Karnak is one of the oldest and greatest. As in Sumer, the temple was the initial form of city in Egypt, as the land, people, ruler, and priests all belonged to the local god of the temple, which thus

became the center of socioeconomic, political, and religious life. Temples owned huge properties, had slave labor working on temple forms, and were the chief money lenders. The classical Greek temples were rectangular with slanting roofs supported by beautiful columns, with a portico at each end or a colonnade extending around the entire building. The temples were east facing, made of marble or other stones, and the central cella housed the image of the deity standing on a pedestal facing the single door entrance; an altar stood outside the shrine. Later temples were collections of buildings including smaller shrines of related minor deities and national heroes, houses for priests, and stalls. The Greek temples of Apollo at Delphi, of Diana at Ephesus, and the Parthenon are the best examples of Greek architecture. The original Roman temples did not have the image of a deity for several hundred years. Influenced by the Etruscans, early Roman temples were oblong wooden structures with a huge inner cella. It was only later, when they came under Greek influence, that they adopted Greek gods at the cost of neglecting their own. The Pantheon, meaning “all the gods,” the most outstanding Roman temple, is a circular building with a huge dome made of concrete. Roman temples had an altar inside the shrine and instead of the colonnade around the entire structure there was a wall of engaged columns. Temple architecture reached its pinnacle in size and splendor during the Roman Empire. The Inca and Mayan temples were generally stair-stepped pyramids with the shrine at the top constructed of stones and decorated with stucco and bas-relief ornamentation. The Temple of Warriors and the Temple of the Plumed Serpent are the best examples of Mayan and Aztec temples, and the Temple of the Sun at Cuzco is the best example of Incan temple architecture.

TENOCHTITLAN

Tenochtitlan was the capital city of the Aztec empire that occupied highland central Mexico during the 14th through 16th centuries. The city was composed of a ceremonial and administrative core surrounded by palaces and residences of the society's elite. Aztec urbanites, numbering as many as a quarter of a million, comprised a diverse array of ethnic groups that immigrated to the city from the distant reaches of the empire and represented a range of specialized occupations, including farmers, artisans, warriors, priests, and bureaucrats. The invasion and conquest of the city by Spanish conquistador Hernán Cortés in 1521 brought world attention to Aztec culture. Since that time, archaeological and historical studies of Tenochtitlan have made significant contributions to anthropology's understanding of pre-Hispanic urbanism in the Americas.

According to Aztec oral tradition, Tenochtitlan was founded by the Mexica people in AD 1325 on an island and reclaimed swamp land near the western edge of Lake Texcoco in the Basin of Mexico. The city was connected to the mainland by three large artificial causeways, which extended from the lakeshore to the city's central civic-ceremonial district that contained the major politico-religious buildings of the capital. These causeways, along with a complex network of freshwater aqueducts, canals, dams, and irrigation and sewer systems, made the city a technological marvel. Beyond the central district were the opulent palaces of the rulers and other bureaucrats, the houses of the nobility, and numerous buildings dedicated to administering the empire. The remainder of the city was composed of urban dwellings of the commoners, some of which were situated upon and surrounded by raised agricultural fields. Tenochtitlan's layout and built environment established the city not only as the geographical core of the empire but also as the conceptual center of the universe.

The central ceremonial district of Tenochtitlan measured approximately 13 hectares and was enclosed by a 30-meter-thick wall called *coatepantli* (“serpent wall”) that was said to have been decorated with representations of serpents. The Spanish priest Bernardino de Sahagún counted 78 different buildings in this district, although only 30 have been archaeologically identified to date. In addition to buildings, numerous sculpted monuments adorned

Source: © iStockphoto/Skip Hunt.

public spaces and sacred places, populating the ceremonial district with representations of key players in Aztec cosmology. For example, the colossal statue of Coatlicue, the old goddess of the earth and mother of all Aztec gods, was erected as a powerful symbol legitimizing Aztec hegemony and rulership. Other monuments record notable events in Aztec mytho-history, such as the monument depicting the dismembered body of Coyolxauqui (representing the moon), who was slain by her brother, Huitzilopochtli (representing the sun), for attempting to kill their mother, Coatlicue. Together, buildings and monuments combined to form a microcosm of the social order and a blueprint of the composite natural/cosmic landscape encompassed by the empire, where worldview and beliefs were materialized and grounded in the physical realities of daily life.

In the center of the ceremonial district rose a giant platform, which served as the principal stage for state religious rituals, including human sacrifice. The raised platform supported a number of buildings: temples, shrines, a school and residence for high priests, a sanctuary for eagle warriors, a ball court, and a large skull rack (*tzompantli*) where trophy heads of sacrificial victims were publicly displayed. The largest building

on this platform was the Templo Mayor (“Great Temple”), a twin-towered pyramid dedicated to the two most important Aztec gods, Huitzilopochtli (god of war) and Tlaloc (god of rain and fertility). The temple was constantly under construction and renovation during the 200-year history of the city, but reached its final height of 45 meters by the time the Spanish arrived in 1519. The building was covered with white lime plaster while the upper temples were painted bright red and blue. The pyramid and its precinct were clearly designed to impress the citizens of Tenochtitlan as well as foreign visitors. By conducting political and religious performances on the summits of monumental edifices, Aztec rulers visually and symbolically reinforced their position at the top of the social ladder. Thus, public celebrations staged within the milieu of the Templo Mayor and the ceremonial district allowed Aztec ruling nobles to capitalize on the physical hierarchy of spatial forms by transcribing the phenomenological sense of ordered spaces into social hierarchy.

Just beyond the central district were the administrative and public buildings, which included a courthouse for judges, a council chamber for war leaders, armories stocked with military arms and equipment, storage rooms for housing surplus from state-sponsored

tribute, and residences for the royal retinue of artisans and entertainers. Surrounding this zone were the palaces and dwellings of the rulers, nobles, and the city's social elite. This area also included extensive gardens and ponds, a library, an aviary, and a zoo.

The palace of the *huei tlatoani* ("great speaker"), the semidivine supreme ruler of the Aztec, measured 40,000 square meters and was finished with painted stucco. It housed his family and other nobles, as well as servants, visiting dignitaries, and government officials. Sahagún observed that the ruler's palace contained rooms where gold- and silversmiths, coppersmiths, feather workers, painters, stone cutters, lapidaries, and wood carvers practiced their trades. The objects crafted by palace specialists were the exclusive prerogative of the ruler. As markers of social rank and status and as items of exchange, these luxury goods acquired importance as a type of politico-symbolic capital; the *huei tlatoani* used these items as gifts to reward clients and attract allies. Yet, as props and costuming, the crafted objects contributed to the strong sensory impression and emotional intensity of state political and religious ritual and confirmed the legitimacy of the *huei tlatoani's* claims to being physiologically superior to other members of society.

Outside of the ceremonial and administrative areas, the city was divided into four sectors: Cuepopan, Teopan, Moyotlan, and Aztacalco. Each of these neighborhoods was subdivided into smaller socioresidential configurations called *calpulli* ("big house")—a group of families related by kinship and friendship that acted as a landholding corporation. As equal and separate entities, the *calpulli* would contribute separately and more or less equally to common obligations of the state; each would separately deliver its part of a general levy in maize or other products to the designated common collection place; in time of war, each contributed a fighting unit under its own leadership. For ongoing duties, however, such as community labor or the delivery of products throughout the year, a scheme of rotation of the *calpulli* was in place.

Families that comprised each *calpulli* lived in walled or fenced compounds in which residential and other types of domestic buildings built of stone masonry enclosed a central patio space. Compounds were connected in various ways by formal streets, informal footpaths, and waterways (canals). This dense, orthogonal grid plan, emanating from the city's center, ordered the residential and commercial zones. Some *calpulli* were home to specific occupational specialists

such as weavers, potters, feather workers, lapidaries, or metalsmiths, while others housed farmers and other food service personnel. The houses of nonelite citizens, built of mud-covered reeds roofed with thatch, were usually located on *chinampa* agricultural plots alongside canals that edged the periphery of the city. *Chinampas* were rectangular raised plots of agricultural land formed of organic-rich sediments dredged from swamps and shallow lake beds. The thousands of plots that surrounded Tenochtitlan provided up to one half or more of the food consumed in the city. Indeed, there were so many plots and canals that the Spanish referred to Tenochtitlan as the “Venice of the New World.” With no plows or draft animals, Aztec farmers used pointed sticks called *uictli* to plant their primary crop, corn, as well as beans, squash, tomatoes, avocados, and a wide variety of chilies and other cultivars.

The urban zone of Tenochtitlan absorbed the adjacent city of Tlatelolco, which was similarly structured with a central civic-ceremonial zone and several *calpulli*. Tlatelolco was unique, however, in that it was organized around the largest marketplace in central Mexico. The Spanish chronicler Bernal Díaz del Castillo observed as many as fifty or sixty thousand people buying, selling, and exchanging an astounding variety of foods; luxury goods made from gold, silver, jade, and turquoise; local and foreign polychrome pottery; cloaks, mantles, and clothing made from cotton or maguey fibers; and slaves exhibited in wooden cages.

By the time the Spanish arrived in 1519, the total area of Tenochtitlan-Tlatelolco encompassed at least 1,350 hectares and contained as many as 250,000 people (estimates of the entire population of the Basin of Mexico range from one million to almost three million). The dual city was composed of a highly diversified population, representing groups from all reaches of the empire. Growth of the city was mostly through immigration, a process actively supported by Aztec rulership with the aim of concentrating the empire’s specialist producers. The city’s expansion was abruptly terminated by Spanish conquistadors in 1521. In the succeeding decades, Tenochtitlan became Spanish colonial Mexico City, with Catholic churches placed atop or adjacent to the foundations of abandoned and demolished Aztec temples.

As one of the few examples of large-scale urbanism in the New World for which detailed written records and material evidence exist, Tenochtitlan has made significant contributions to theory in urban

anthropology. Archaeologist William Sanders has attributed the early development of urbanism in this region to intensive cultivation and specialized agricultural adaptations (*chinampa* farming), which developed as a result of population pressure on land and the resource base. Incorporating the ideas of V. Gordon Child, Julian Steward, Karl Wittfogel, and Robert Carneiro, Sanders and his colleagues posited a materialist, cultural-ecological model, arguing that circumscription, competition, and differential access to strategic resources served as the basis for the development of stratification and social classes, market exchange, tribute extraction, and political centralization in the Aztec empire. More recent research by Elizabeth Brumfiel, Michael Smith, Deborah Nichols, Leonardo López Luján, and others has demonstrated that the cultural-ecological model does not necessarily account for all of the variation in settlement type, size, and distribution. Instead, archaeologists now tend to approach Aztec urbanism from a regional perspective, emphasizing the dialectic between social and natural landscapes and the role of city-states, market dynamics, imperialism, and ideology and ritual.

Terra Amata is an open-air Lower Paleolithic, or Early Stone Age, site on the Mediterranean near the delta of the Paillon River in present-day Nice, France. Henri de Lumley, a 20th-century French archaeologist, excavated the site in 1966 prior to the construction of an

apartment building, the lowest floor of which now houses the Terra Amata Museum. Terra Amata is perhaps best known for producing evidence of some of the first artificial structures in the world. De Lumley identified hearths, post holes, and limestone blocks arranged in such a way that, when combined with the distribution of artifacts at the site, suggested the presence of temporary oval-shaped structures measuring 7–15 meters in length and 1–6 meters in width. Some structures contained the imprints of animal skins that are hypothesized to have demarcated working areas inside the structure.

The site was originally dated by the thermoluminescence method to 214,000 BP and 244,000 BP, respectively, for an average date of 230,000 BP. However, sediments from the archaeological layers at Terra Amata were recently dated by the electron spin resonance method to 380,000 BP, which indirectly indicates it may be older than previously thought.

Terra Amata is a deeply stratified site with archaeological materials distributed throughout three major levels referred to as—starting with the earliest—the Lower Cycle, Beach, and Dune layers. During the excavations there, de Lumley thought he had identified 27 distinct living floors with six in the Lower Cycle, four in the Beach, and eleven in the Dune. Paola Villa's 1983 reanalysis of Terra Amata revealed a much more complicated depositional history. Villa examined site formation processes at Terra Amata based largely on an analysis of refitted stone artifacts and identified a high degree of vertical displacement of artifacts from one level to another. This observation led Villa to conclude that de Lumley's stratigraphic divisions were largely arbitrary and did not correspond to distinct anthropocentric levels of the site.

The maximum habitation area at Terra Amata measured approximately 100–150 square meters, though the density and distribution of artifacts in some levels suggested much more limited occupations. De Lumley excavated most of the site and recovered almost 10,000 stone artifacts of the Acheulean Tradition, which is a stone tool tradition associated with *Homo erectus*. The Acheulean artifacts found at the site consisted mainly of large choppers, expedient unifacial tools, and flake tools made of pebbles and other stone raw materials that originated at the site itself. In addition to an abundant artifact assemblage, ecofacts like animal bone, charcoal, coprolites (i.e., paleo-feces), and mussel shells were also recovered. In fact, one level of the site produced 43 coprolites.

Although the remains of animals hunted and consumed by the hominids occupying the site were abundant, they were very fragmentary and not well preserved. Species diversity was high and included elephant (which was the most common), red deer, wild boar, aurochs, thar, bear, and rhino. A small proportion of mussel shells were also identified among the animal remains, however it is unknown whether they were intentionally collected or if they are a natural occurrence.

Coprolites preserved in the Dune stratum contained the pollen of plants that flower in the late spring and early summer, suggesting Terra Amata was occupied at that time of the year. There is anecdotal evidence, particularly in the animal remains, suggesting late fall occupations as well. Regardless of when it was occupied, the artifacts, ecofacts, and structural remains point to occupations of limited duration by nomadic hunter-gatherers during the Lower Paleolithic.

Territoriality involves rights to specific locations or bounded areas and the resources and activities within them. Our assumptions about territoriality often are shaped by the contemporary nation-state, which lays claim to a large number of rights over a large, unitary, and bounded territory. Also, we may well be influenced by the concept of private property, involving a high level of exclusive rights over real estate, subordinate in most cases only to the nation-state. Indeed, extreme possessiveness and exclusiveness is, at times, assumed to be human instinct. Cross-cultural and

cross-historical evidence from anthropology shows, however, that the phenomenon of territoriality is more complex, variable, and changeable.

Studies of primate social organization suggest that there are biosocial roots of territoriality, but each species has its own pattern and there is a great deal of variation by habitat within species. Probably the most useful generalization is that species-specific patterns of territoriality and social organization are closely connected. In small-scale human societies, territoriality was not a matter of bounded, exclusive spaces, but one of diverse, socially organized rights to movement, products, and located ritual activities. Indeed, exclusion was probably less important as an organizing principle than choosing appropriate means of access. Small-scale societies are woven together by complicated networks of kinship (real and fictive), ritual brotherhood and sisterhood, marriage exchange, and gift-giving friendships. Each provide means for asking responsible parties (the “owners”) for rights to visit and use space and resources. This is consistent with the high degree of mobility and flexibility in such societies.

The bundling together of rights and association of them with bounded territories emerges as a correlate of social stratification and, especially, the state. Pre-modern states often made impressive claims to territory, about which we should be cautious. They lacked the technological and organizational capacity to control many territories, often relying on local proxies for real control. States were preoccupied with key cities and specific trade routes to high-value, low-bulk resources, as well as fortified outer shells along boundaries with autonomous mobile populations. Complex vertical and horizontal frameworks of aristocrats and peasant communities governed most rural areas, and a great deal of ethnography has documented these as kinship/residence rules.

Contemporary territoriality (bounded national territories and private real estate), then, is quite distinctive. The creation of this territorial framework required considerable struggle and change in the last 200 years. Changes include the destruction of feudal privileges inside the nation-state and the establishment of direct bureaucratic governance across its space, as well as the development of citizenship, rights of insiders within the national territory, effectively also instituting the outsider status of “alien”—visitors or migrants. Through enclosure, older collective rights to land and resources were ended and the space

converted into individual property. Nor has this transformation ended. Under current conditions of globalization, wealthier and more privileged populations can move across national boundaries while poorer populations are more restricted or move illegally, and new private property regimes include an increasing range of distinctive spatial rights (gated communities, etc.).

TERRITORIALITY IN PRIMATES

A territory is an area of space that an animal defends as exclusive property. As with other species, primates mark their territory through feces, urine, loud calls, and shrill hisses.

Territoriality is particularly strong in primates, who often resort to extreme violence to defend their territory from any perceived threat. Studies on territoriality in primates have led to the conclusion that chimpanzees can be as violent as humans. Scholars have also revised the notion that lethal group-against-group violence is a uniquely human behavior. As primatologist Jane Goodall suggested in her accounts of “warfare” among neighboring groups of chimpanzees, when it comes to aggression, the dividing line between humans and the rest of animal species is not clearly drawn.

The study of primates’ defense of their own territory has provided a compelling counterargument to the established assumption that human violence is either the consequence of instinctive biological urges or deviant behavior provoked by social problems such as overcrowding and poverty. Instead, newer researches suggest that

aggressive behavior is a complex and intertwined combination of both. Researches on primates' territoriality has also proved that group violence and social cohesion are inextricably linked. Only when a group of male chimpanzees has formed a solid alliance between themselves do they attack neighboring territories for access to females and land resources such as water. Although humans are far more sophisticated in their cooperation, technology, and the kinds of resources they fight over, the evidence that apes form coalitions to defend and attack the territory of others suggests that all primate aggression, including human aggression, is more complex than an explosion of animal instincts.

In contrast to group-against-group conflicts, aggression against a single primate that has just reached the territory of the group regulates social stability. Among several types of monkeys, for example, the most aggressive encounters take place when a newcomer tries to join an established group. Newcomers must find their way into the hierarchy and, once they are established in the group, the level of aggression drops considerably, as each individual generally defers to those higher on the societal ladder. To be accepted in the new territory, a monkey should count less on its physical strength, aggressiveness, or fighting skills than on its ability to make friends. Older males often maintain their social position by cunningly associating themselves with other influential monkeys in the group.

Understanding primate violence as result of territorial violation can shed light on several human violent behaviors, and some scientists are even proposing that it could offer keys to the problem of violence in inner cities.

— Luca Prono

TEXTILES AND CLOTHING

Textiles are woven and knit fibers and yarns that are twisted up in order to produce materials that are used every day. Human society produces numerous objects from the technology of textiles, for example, towels,

sheets, carpet, clothing, toothbrushes, and upholstery. Also included are objects that use textiles to reinforce structures such as vehicle tires, bridges, and buildings. Textiles are created by the accumulation and combining of textile fibers. Different fibers are more suitable for certain textile material use than others. Carbon fibers, for example, are not suitable for products such as clothing, but are suitable for use in high-technology products and sports materials. Specific fibers may be used depending on their characteristics and advantages. Nylon, silk, and rayon were used in dress hosiery because they contained characteristics of elasticity and comfort against the human body.

Yarns are constructed through the assembly and twisting of fibers, forming a continuous strand. Again, there are many types of yarns that can be created depending on the twisting and quantity of yarns being used. They may be thin or thick, soft or rough to the touch, strong or more delicate, depending on the fibers being used in the process. The transformation of textile into material involves the use of knitting needles, a crochet hook, or a hand loom, or from modern technology, machines that knit or stitch to produce extravagant textile materials.

The next step in textile production is the finishing and coloring of the material that has been created. There are numerous techniques that can be used to create the desired qualities. These include processes such as flame retardants, stain-resistance applications, applications that reduce static cling, and so on. Color may be added through dye and decorations or patterns may be printed directly on the material.

The History of Textiles

There are several suggestions about the point at which textile production began. Most people agree that there is no concrete evidence that signifies the origin of textile creation. However, remnants of woven material have been found on clay pots dating back 27,000 years. It was previously believed that the history of textiles began with the discovery and use of the needle among the European Gravettian, mammoth-hunting peoples of Eastern Europe and Russia around 26,000 to 20,000 BC. The needle allowed cultures to bind objects, such as animal hides, together while attaching other objects, such as stones, shells, and teeth. Small bones were often substitutes for needles among hunters and gatherers. During the Stone Age, vines, guts, and sinew were used to string beads,

stones, and teeth. The oldest fragment of cloth was found in Cayonu, southern Turkey, dating back to around 70,000 BC. Given that domestication of plants and animals would not have existed, early textile production used materials found in nature. The process of felting is believed to be a prehistoric method of producing textiles. It does not require any stitching or weaving; instead, fibers such as wool are molded into shape using a combination of moisture, heat, and pressure.

Nomadic herding, fishing, and farming people frequently used bast fibers and twisted gut in manufacturing ropes, reins, meshes, and nets. These, combined with reeds, grasses, and sampling rods, are thought to be the earliest forms of the manipulation of materials in the textile creation process.

Methods of dyeing material were present during the Bronze and Iron ages (between 3000 BC and 400 BC). Evidence of dyeing practices has been found in Egypt, Switzerland, and Peru. The Paleolithic people were among the first people to use dye (ochre) to decorate parts of the body and bones of the dead. Other dyeing methods followed such as murex shellfish dyes, indigo, and woad. Later, metallic manipulation was used to tint colors. This is evident among the Persians, who used copper and cast iron boiling vats during the dyeing process. In southern Asia and the East Indies, turmeric and safflower were also used to dye cotton, linen, and silk.

Art was integrated into the production of textiles by the use of ornamentation to add aesthetically pleasing elements and patterns. Beads, tassels, loops, and embroidery began to decorate textile material, allowing for more intricate designs and unique expressions. In Turkey, beads were found among textile instruments dating as early as 2300 BC. Beads have also been discovered in other parts of the world including Egypt (dating from 1800 BC) and sites belonging to the Mycenaean Crete (dating from 1450–1300 BC).

The Māoris, Peruvians, Mesoamericans, and the North American Natives used complex twining techniques to attach feathers to objects. In Spain, baskets, sandals, bags, and caps have been found that date from 3000 BC and were manufactured using twining, plaiting, and weaving techniques. Subsequently, between 1200–800 BC, there was an emergence of fine and regular weaving, which suggests the invention of the heddle rod.

The exchange of textiles, mainly cloth, dates back to sometime after 1500 BC, when workers would

trade textiles within their groups or communities. Thus began the trade movement that would increase as populations expanded and villages grew into towns. Before 750 BC, due to the benefits of trading textiles, a large portion of fabrication was produced for commercial trade and not for necessity. Textiles were desirable possessions, especially Chinese silk. There is evidence of Chinese silk in Egypt as early as 1000 BC. Chinese silk and cotton were also favored by the Romans.

It has been suggested that America was discovered as a result of the desire to import and export spices and textiles to and from the Orient more rapidly. Once America became established, it too joined the textile trade. With interests increasing on an international level, there was a high demand for new and improved techniques in textile production. Textile production was the first area to undergo industrialization during the Industrial Revolution. Inventions such as spinning machines, automatic looms, and the cotton gin were of great importance in upgrading the quality of textile production. The early 19th century brought even more new ideas and innovation to the creation of textiles. Synthetic fibers and dyes were introduced and rayon was created. The year 1910 marked a new era; this was the year nylon began to be manufactured in mass quantity. The first manufacturing plant was in the United States.

The History of Clothing

The evolution of textiles had a tremendous effect on cultures worldwide. As the textile industry grew, so did the significance of clothing. Clothing is believed to be a means of expressing a people's identity, or at least fragments of their lives. Clothing has different meanings to different cultures. It is impossible to fully understand a culture through clothing, but it is possible to get a glimpse into certain aspects of people's lives through the textiles they used and the clothing they wore. Some believe that by examining the changes in clothing worn by a culture, one can understand the culture's social transformations.

Clothing is defined as items or substances that cover the body from head to toe for decoration or protection from the elements. It is apparent that clothing has a unique function in each society, as evidenced by the particular outfits and dress that are worn for different events during a person's life. Most societies have specific clothing that is worn during

special ceremonies, such as initiations, or spiritual and religious events, such as marriage and burial ceremonies.

There are several theories concerning why societies wear certain clothing and how clothing originated. Ruth Benedict explains that there is not any one reason why clothing becomes a part of a culture's practice; in fact, there are probably several acceptable explanations. Explanations are bound to differ depending on the location and the characteristics of the culture and geographic conditions. She does, how-

Source: © iStockphoto/Matthew Brown.

ever, discard the theory that cultures began to wear clothes due to their modesty. Benedict stresses her belief that covering up revealing areas alone, or areas of a sexual nature, would in fact bring more attention to them, therefore the theory seems to be inaccurate.

Some speculate that clothing originated out of superstition and ideas of magic, to conceal a body part from evil or prevent spells being cast upon it. Others suggest that clothing originated out of necessity, to battle the severity of the climate and environmental conditions. In colder climates, there is evidence that tribes used animal skins to survive the harsh conditions. Clothing had much more to do with utility than style and fashion.

There are other theories concerning the origin of the use of clothing. Ornaments and amulets such as shells, teeth, and skins eventually were of economic importance and reflected wealth and power. There is an ornamentation hypothesis that proposes that ornamentation led to the use of clothing. Ornaments were popular among Brazilians and the central Australians. They did not possess a great deal of clothing but did, however, acquire a great number of ornaments. There would be more ornaments worn during ceremonies or on special occasions. In the Andamans, the natives decorated the body with scarification and painting as well as ornaments. Ornaments are objects that convey aspects of an identity, including sexual attractiveness, power, and social, religious, or political status.

Clothing may be used at times to distinguish an individual's origin. Fernand Braudel states that clothing

or dress can be used to decipher concepts of time consisting of enduring time, social time, and social history. An example of this is the Mayan dress called the *traje*. The *traje* remained unchanged for quite a long period, and it could be identified with a specific region. To wear a *traje* was to indicate that one was Mayan.

Sometimes it is not the everyday clothing that indicates a difference within a culture but the clothing worn during special ceremonies. For example, the Bunu Yoruba people may wear the same everyday clothing as other Yoruba groups, but will wear different clothing for special occasions or ceremonies such as marriages or funerals. For the Yoruba, clothing also specifies gender and power relations. White clothing is usually worn by men, whereas black clothing is worn by women. This cultural distinction in the style of clothing is currently more difficult and unreliable due to globalization and the rate at which trade has allowed the exchange of clothing and textiles. Dress or clothing is now available in a variety of areas and has no boundaries or limitation.

Clothing is not static. There has been an evolution of clothing from the moment of its existence. Some suggest that missionaries in colonial times influenced the change of dress within indigenous cultures. The missionaries not only brought with them the message of God but also clothing and other objects, in hopes of converting those cultures. This did not always work. Some cultures changed their clothing while others continued to wear their traditional dress.

Clothing has evolved due to the continuous technological advances in the textile industry that provide ever more fabrics, textures, colors, and styles to choose from. Since the Industrial Revolution it has been easy to obtain material and clothing from all over the world, and today's fashion trends integrate many multicultural characteristics. Although clothing has dramatically evolved, in many parts of the world cultures continue to follow their customs of wearing specific clothing for special ceremonies.

THEORIES

Theory, from the Greek word for viewing or contemplation, has played a significant role in the understanding of science since the early 19th century but was not considered central before then. Instead, philosophers and scientists spoke more often of (Natural) Law and of hypothesis, defined by Mill as “any supposition which we make (either without actual evidence, or on evidence avowedly insufficient) in order to endeavor to deduce from it conclusions in accordance with facts which are known to be real.” As philosophical interpretation became more language based and conceptually analytical, however, theory became more important in the analytical tradition of science, and in the Marxist tradition, theory (*theoria*) was often contrasted with practice (*praxis*), following Marx in the *Theses on Feuerbach*.

In the period following Einstein and Darwin, however, “theory” became a term that applied to a set of laws and hypotheses that were well-attested, coherent, precise, and covered all of the explanatory domain in question. Hence, Einstein's general theory of relativity

is understood to cover all dynamics previously covered by Newtonian physics, with the added benefits of improved accuracy and precision and increased coverage of phenomena that Newtonian physics could not explain. Theories replaced earlier theories, it was held, in particular by the philosophical school known as the Logical Positivists, or the Vienna Circle, on rational grounds, and this replacement was absolute progress.

Popper's Account and Theories as Explanations

Theories were thought at this time to be constructed on the basis of evidence through logical induction—generalizing from observed instances to formulate universal claims. This set up the Problem of Induction, which David Hume had first formulated in the latter part of the 18th century, and Karl Popper revived as a problem in 1934, in his *Logik der Forschung* (“the logic of research,” unfortunately titled *The Logic of Scientific Discovery* when published in English). Popper observed, as Hume had, that a universal claim cannot be derived from any finite number of observations and so cannot be rationally justified or verified, as the positivists had sought to do. He defined theories as “universal statements . . . nets cast to catch what we call ‘the world’: to rationalize, to explain, and to master it.” Theories explained events by giving a deduction from their universal laws and singular initial conditions that described the event to be explained. Carl Hempel generalized this as the *nomological-deductive model* of explanation. Variations for law-like generalizations that were not exceptionless universal statements, and for stochastic and probabilistic inferences, were also developed by Hempel and others. In particular, a historical form of explanation worked, so to speak, in reverse: if you could produce a law-like generalization from which, together with some initial and boundary terms, you could deduce (or induce or infer in some manner) the events that were recorded, then you had offered an explanation of the events—the so-called *covering law model*. If there were more than one generalization that covered the event, then the best theory was the one that covered the most events or cases. Prediction was not possible in historical science, of course, but *retrodiction* or the “prediction” of already known events from the covering law explanation was considered to be equivalent logically to prediction in the experimental and present sciences.

Social Accounts

Falsificationism, as Popper's view was called, underwent several revisions under challenges that to falsify a particular hypothesis meant to accept that several ancillary hypotheses had to be accepted, and that a negative result might in fact falsify them instead (known as the *Duhem-Quine hypothesis*). One reaction, by Feyerabend, asserted extreme methodological anarchism under the slogan "anything goes," basically allowing a scientist to use or assert anything she liked, from creationism to astrology, in explanation. Feyerabend may have intended this as a gadfly or as a piece of revolutionary thinking. In this, he focused on the political and social nature of science and its theories; they were to be regarded as serving the political and social interests of the wider community.

Later accounts of the nature of theories arose from a reaction to Popper's falsificationism. Thomas Kuhn, in the tradition of historians of science like Merton, proposed that scientific theories acted as global *paradigms*, a term he later came to replace with several different terms that more exactly expressed the various roles "paradigm" played in his account of science. Kuhn proposed that science alternated between "normal science" and "revolutionary science." During normal periods, a theory acted as a guiding principle in which its terms set out the ontology of the domain under explanation. Methods, viable explanations, disciplinary boundaries, and even reality itself was specified by the theoretical paradigm (the latter being an extreme overinterpretation of Kuhn's ideas). In short, a theory was an entire worldview, and during revolutions there was an incommensurability of terms, ideas, and methods that, in effect, made progress and communication difficult, if not impossible.

After Kuhn, Lakatos proposed that science consisted of "*research programmes*," which were open to revision at the edges but consisted of a core of protected hypotheses. Unlike Quine's earlier *reviseability thesis*, which asserted that nothing was protected from rational revision, Lakatos held that any research program had a number of unreviseable theses or theories. These acted as the center of a research programme, which could either be *progressive* or static. A progressive research program was a sign of an active science.

Structural Accounts

Subsequent ideas about theories in the philosophy of science have not been as widely discussed in the social

sciences as the ideas of Kuhn and Popper, which have tended instead to follow in the tradition of Foucault, Derrida, and other continental philosophers, whose accounts tend to treat theories more as social constructs and ideologies. However, there have been several attempts to make the notion of a theory more exact in the analytic tradition. Attempts were made by several logicians to formalize Kuhnian theory as set theoretical structures, hence the name Structuralism (not to be confused with the French philosophical movement).

A more general and novel attempt to formalize scientific theories was undertaken by Suppe and van Fraassen, whose view of science was based on it being a collection of *models* that were semantic structures. The *semantic conception*, as it became known, treated theories as explanatory conceptual structures in a mode similar to the N-D models, but added that theories were interpreted semantically, so that the model itself was insufficient as an explanation until all the terms had been assigned referents. The semantic view also treated theories as restrictions on the field requiring explanation—to propose a theory was to specify the explanatory domain it was to cover. A similar account of theoretical explanation as being a position held in a contrast space of alternatives was developed independently in the social sciences by Garfinkel.

Currently, a theory is regarded in the philosophy of science as a conceptual entity that plays an explanatory role in a science. Rosenberg defines it as a "relatively small body of general laws that work together to explain a large number of empirical generalizations, often by describing an underlying mechanism common to all of them." A movement known as the New Experimentalism treats a theory as a summary of empirical observations based upon experimental interaction with physical objects.

Theory Reduction

A theory that "reduces" to another theory is regarded as having been supplanted by that theory, which is regarded as progress. The reducing theory is expected to have a wider coverage of phenomena or explanatory domain than the theory it reduces. A number of critics have rejected the ideal of explanatory unity of the sciences, particularly in biology, and deny that reduction is either inevitable or desirable. In particular, *genetic reductionism* in psychology is regarded as

flawed. This parallels the question of methodological individualism in the social sciences.

Theory in Anthropology

Anthropologists usually mean by “theory” a *particular* theory—a functionalist, structuralist, or socio-ecological theory of social systems, for example. However, while “social facts” have been defined by Durkheim, along with method, and similar ideas used in other sociological theory traditions, the notion of a theory has been treated as something obvious or self-evident. How to test or formulate theories in general has been assumed or passed by, in general, and the ways in which theories explained their subject have been left unspecified.

Physical anthropology tends to rely on conceptions of theory building and testing from the physical and historical sciences. Cultural anthropology has often relied upon conceptions taken from critical theory or social constructivism, in which a theory is something constructed either by the researcher or by the community of which the researcher is a part. Mixed conceptions of theory are rare.

THOMAS, ELIZABETH MARSHALL (1931–)

Elizabeth Marshall Thomas was born September 13, 1931 to Laurence K. Marshall, founder of Raytheon Corporation, and Lorna McLean Marshall. She grew

up in Cambridge, Massachusetts, graduated from Abbot Academy in Andover, Massachusetts in 1949, and then attended Smith College in Northampton, Massachusetts. After one year at Smith, her father retired from Raytheon and led the family on an anthropological expedition to the Kalahari Desert in southern Africa. The Marshall family was among the first to meet and study the Bushmen. They returned to the Kalahari many times in the next few years and often stayed for up to a year. From notes that she took during her experiences, she wrote *The Harmless People* (1959).

In 1954, Elizabeth Marshall Thomas graduated from Radcliffe College in Cambridge, Massachusetts with a degree in English. As a student, she wrote a fictional account of the Bushmen that won a short story contest in *Mademoiselle*. “The Hill People” was later published in the *Best of American Short Stories of 1953*.

In 1956, she married Stephen Thomas. They have two children, Stephanie and Ramsey. With them she returned to Africa to study the Dobo people. Her account of these experiences was titled *Warrior Herdsmen* (1965).

Although Elizabeth Marshall Thomas was not trained as an anthropologist, she keenly observed and recorded the lives of the Bushmen of the Kalahari Desert of southern Africa. In her account of these experiences, she presents a clear picture of the customs and the daily lives of a people living in very primitive conditions. The hunting and gathering activities are clearly described in a style reads as a novel rather than an ethnographic (anthropological) study. Hunters, vain young women, young boys, older women, the landscape, the plants and the animals are vividly portrayed. The reader is caught up in the everyday life and drama of the Bushmen as well as their ongoing struggle for survival.

Over the years, Elizabeth Marshall Thomas has written many articles and books including some novels. Most recently she published *The Hidden Life of Dogs* (1993) and *The Tribe of the Tiger* (1994). Most fascinating of her novels is *The Reindeer Moon* (1987), which is the story of a young girl in a prehistoric culture. Using knowledge that she gained from living with and observing primitive societies, Marshall Thomas was able to create a virtual culture and lifestyle of persons living in precarious situations. Elizabeth Marshall Thomas is a keen observer of the lives of others. These observations have done much to advance the knowledge of the Bushmen of the Kalahari Desert.

Her novels are important because they translate her observations of human life into believable fictional cultures. It is well worth one's time to read and study Thomas's work.

HOTTENTOTS

Hottentots are a people who live in southern Africa. When the first Europeans (Portuguese) came to the Cape of Good Hope, they found tribes with a Stone Age culture.

The Dutch who settled the area called the natives either "Bushmen" or "Hottentots." Those who lived in the remote rural areas and hunted in the bush they called Bushmen. Those who lived in more settled situations and herded livestock they called Hottentots.

The name *Hottentot* is believed to have come from the language of the Hottentots, which uses several kinds of clicking sounds. The name is probably onomatopoeic imitation of the four ways they make clicks into a staccato-sounding speech. The Hottentots call themselves *Khoikhoi*, which means "men of men."

Scholars believe that the Hottentots migrated from a northern part of the Great Rift Valley in East Africa several millennia ago. They wore a skin cloak (*kaross*) and were described as peaceful people with brown skin and of medium height. They were organized into tribes and clans headed by a chief.

Descriptions of the religion of the Hottentots report that they worshipped a superior being but were mainly ancestor worshippers. They also honored the moon and engaged in a variety of

rituals, especially dances. Hottentots engaged extensively in witchcraft and used herbs for medicine and as intoxicants.

Some Hottentot women have been observed to have external genitalia and secondary sexual characteristics that are unique. Specifically, some have masses of fat, extended *labia minora*, and elongations of the *praeputium ditioridis*.

Originally, there were several different groups of Hottentots, but they have mostly died or been absorbed into newer immigrant populations. Many are now in Namibia.

In the 17th century, the Hottentots fought two wars with the Dutch settlers. The Hottentot war strategy was to destroy the economy of the Dutch by running off their cattle, but the natives failed to understand the economic power of the Dutch. In 1713, a smallpox epidemic killed a great number of the Hottentots.

In the 20th century, the term Hottentots was disparagingly used as a synonym for "exceedingly primitive."

SAN BUSHMEN

The words *San* and *Bushmen* are used to identify an indigenous people of southern Africa related to the Khoekhoe. They live mainly in Botswana, Namibia, and southeastern Angola. Bushmen is an Anglicization of *boesman*, the Dutch and Afrikaner name for them, although anthropologists now prefer to use the Nama word for "bush dweller": *saan* (plural) or *saa* (singular).

Despite what was first concluded by researchers, the San are not easily identifiable by physical features, language, or culture. Today, they have become largely undifferentiated from the Khoekhoe or their Bantu-speaking neighbors. Yet in the past, a distinct San culture existed and still survives in limited groups. San culture is centered on bands of people, and each band usually includes several families, between 25 and 60 people total. Bands

are not self-contained entities. On the contrary, there is considerable interaction through trade and particularly marriages so that the movement of people from band to band is comparatively frequent, and the composition of bands varies considerably in time. Each group has its own territory, and its decisions are influenced rather than imposed by older members. Many of the rural San live in lightweight, semicircular structures of branches tied with twigs and thatched with grass. Their rock art, which persisted well into the 19th century, is particularly fascinating, as it is not merely decorative. Scholars concluded that this art had a powerful ritual significance and has been associated with the trance dance and trance experiences of shamans.

At the turn of the 21st century, the San numbered about 100,000, with the majority living in the western Kalahari districts of Botswana. Namibia had the next largest group, and about 10,000 lived in southeastern Angola. In the new millennium, court cases have been fought by the San against their national governments. The Botswana government, for example, has faced several trials because of its decision to evict San tribes from their lands in the Central Kalahari Game Reserve, offering goats and cattle in exchange. Yet as one of the San spokesmen countered, people who have been hunters all their lives cannot be expected to become farmers overnight. Despite the reassuring statements issued by Botswana President Festus Mogae to the international community, the San continue to be persecuted and risk being imprisoned if they return to their ancestral land.

TIERRA DEL FUEGO

Tierra del Fuego (“land of fire” in Spanish) is the southernmost tip of Argentina and Chile’s southern Patagonian territories. It is an archipelago that consists of a large island, called Tierra del Fuego as well, and a group of smaller islands separated from the continent by the Strait of Magellan. Half of the large

island, and the islands west of it, are part of the Magallanes region of Chile. The eastern part of the archipelago belongs to Argentina. The archipelago of Tierra del Fuego is surrounded by the Andes mountains and the south Pacific Ocean to the west, the plateau of Patagonia and the waters of the south Atlantic Ocean (Mar Argentino) to the north, and the south Atlantic Ocean to the east. Ushuaia, the southernmost city on the continent and the capital of Argentina’s province of Tierra del Fuego, is located on the Beagle Channel that leads out to sea and on to Antarctica.

The Spanish conqueror Hernando de Magallanes (Ferdinand Magellan) disembarked in Tierra del Fuego in 1520; however, the region was not fully explored until the early 19th century. In between, the official cartography identified the whole Patagonia area as secluded indigenous territories. The region, then, became known as “the edge” and its natives as inhabitants of the utmost end of the earth. It is not surprising that due to this metaphoric view of Tierra del Fuego, European explorers and conquerors engaged in expeditions in search of virgin lands and new commercial opportunities. Between 1826 and 1830, the English explorer FitzRoy landed in the Beagle Channel, which connects the Atlantic and Pacific Oceans. The naturalist Charles Darwin accompanied FitzRoy on one of his expeditions. It was particularly during this journey that Darwin began to formulate the theories later published in *The Origin of Species* (1859).

At the time of the first European native contact, four aboriginal groups inhabited Tierra del Fuego. The *Onas*, or *Shelk’nam*, in the northern steppe grassland had a pedestrian-hunter economy with the guanaco as their most important resource; the *Yaganes*, or *Yámanas*, in the region of the Beagle Channel, whose sustenance was based primarily on sea lions and the use of canoes; the *Alakalufs*, in the southwestern Chilean archipelagos, with a *Yaganes*-like economy; and the *Haush*, or *Manekenk*, on Península Mitre, at the eastern tip of Tierra del Fuego. The latter group subsisted on terrestrial and sea mammals. Although there is still much academic debate about the biological origins of these ethnographic groups, the diversity in their morphological characteristics surprised not only Charles Darwin but also ethnographers and travelers alike. Indeed, some scholars suggest that it is this diversity that provides accounts of the evolution and historical settlement of people in the Americas.

Source: © Royalty-Free/CORBIS.

Also, research suggests that this diversity is rooted in the varied geographical characteristics of the environments in which they live, and in their diets. Today there is almost no representation of these groups other than their fully assimilated and ethnically mixed descendents.

From atop Tikal's Temple IV, a structure that soars 65 meters into the air, it is possible to view one of the largest pre-Columbian Maya sites and its surrounding environs. Today, the jungle has reclaimed ownership of the city's buildings, which were so carefully constructed by Tikal's ancient inhabitants. Throughout the Classic period, however, Tikal was an important political regional capital with a reach that extended throughout the Maya world and beyond its borders.

Tikal's earliest known occupation dates to 800 BC, after which the site grew in size and population. The urban core includes the Great Plaza, ringed by the North Acropolis, Central Acropolis, and Temples I and II. To the west are Temples III and IV; additional structures include Temples V and VI, the South Acropolis, and the East Plaza. Excavations at the North Acropolis have revealed a long history of building renovations and information about the trajectory of the dynastic line, both of which commenced in the

Late Preclassic period (ca. 250 BC–AD 250). The North Acropolis became the focus of long-standing royal interment and ancestor veneration as indicated by rich funerary remains, portraiture, and hieroglyphs.

During the Late Preclassic period, Tikal's rulers sustained contact with Teotihuacán in central Mexico. Architectural style, artistic motifs, dress, and mortuary practices at Tikal attest to Teotihuacán's influence. The Mundo Perdido (Lost World) Complex at Tikal, for instance, included a pyramid (Structure 5C-54) initiated in the Late Preclassic period and constructed in the talud-tablero architectural style. The sloping wall and flat top style is ubiquitous at Teotihuacán. Interaction with Teotihuacán continued into the Early Classic period (ca. AD 250–600) and may have legitimated Tikal's position of prominence in the Maya lowlands.

After Teotihuacán's Early Classic demise, Tikal's rulers continued to assert power over, and forge links with, many neighboring rivals. However, competing Maya polities' militaristic maneuvers and political intrigues began to significantly undermine Tikal's

dominance during much of the center's later history. Specifically, in the mid-6th century, Lord Water at the Belizean site of Caracol led a successful military campaign against Tikal, capturing and killing the ruler Double Bird. In the aftermath, known as the "hiatus," Tikal's monuments were defaced and dismantled, population growth halted, sociopolitical structures fragmented, and economic stability wavered.

Erection of new temples and twin pyramid groups in the 7th and early 8th centuries indicates renewed fortunes at Tikal. The twenty-sixth ruler, Jasaw Chan K'awiil (also Ruler A or Ah Cacau), who was entombed beneath Temple I, was responsible for this turn of events. For example, the defeat of Calakmul's ruler Jaguar Paw by Jasaw Chan K'awiil reaffirmed Tikal's reemergence as a power with which to be reckoned. Despite these gains, archaeologists believe that by the mid-9th century Tikal's central authority had waned and residences were abandoned. Collapse was not

the result of a single event but most likely caused by combined phenomena like environmental degradation, social unrest, warfare, and political instability. Gradually, the jungle reasserted its status as Tikal's primary tenant. This important site, however, continues to yield new information. Combined archaeological efforts and decipherment of glyphic texts enrich understanding of Tikal's history, its dynamic role in political events of the Classic period, and the cultural legacy it imparted upon pre-Columbian and contemporary Maya peoples.

TIKAL

Tikal, which means “city of voices,” was the largest urban and ceremonial center in the southern Maya lowlands that now correspond to the northern part of the region of Petén, Guatemala. Its ruins, surrounded by a vast rain forest, constitute the central attraction of the Tikal National Park, established in the 1950s and designated a UNESCO World Heritage site in 1979.

The city was first founded as a small village during the Middle Formative Period (900–300 BCE), but became an important ceremonial center in the Late Formative Period (300 BCE–AD 100), when major pyramids and temples were built. Tikal prospered during the Late Classic Period (AD 600–900) thanks to successful military conquests and the expansion of its commercial activities. Its huge plazas, pyramids, and palaces, which have now become its distinguishing feature, were planned in this period. Maya art flourished in the city with monumental sculpture and vase painting. The appearance of Maya hieroglyphic writing and a complex systems of time-counting date back to this period, too. At the height of its prosperity, the heart of the city was populated by more than 10,000 people, with a total of 50,000 inhabitants in the surrounding areas. After this economic and artistic peak, the city suddenly declined and, as other major centers of the southern lowlands, was abandoned by the 10th century. The reasons for Tikal’s decline are still unknown and the history of the city’s governments also remains ambiguous.

— Luca Prono

Tikopia, a Polynesian community near the eastern border of the Solomon Islands, is arguably the most thoroughly documented small-scale society in the ethnographic record. That documentation exists primarily as a result of investigations by Sir Raymond Firth in 1928–29, 1952, 1966, and 1973. Based on those four field visits, he published nine full-length books and countless articles. In addition to Firth’s path-breaking research, studies of varying length have been conducted by social anthropologists James Spillius, Torben Monberg, Eric Larson, and Judith Macdonald; ethnobotanist Douglas Yen; and archaeologist Patrick Kirch.

Tikopia is a “Polynesian outlier,” meaning that its people are linguistically, culturally, and physically Polynesian, although their home lies outside of what we normally think of as the Polynesian heartland—a vast triangle bounded by Hawai’i in the north, Rapanui (Easter Island) in the east, and Aotearoa (New Zealand) in the west. It is located at 12° 18' S by 168° 48' E. Tikopia’s climate is tropical. Its yearly calendar is divided into two seasons, generally termed the “trade-wind” and “monsoon” seasons (in Tikopian, *te tonga* and *te raki*, respectively). The trade-wind season, running from somewhere in April to October, is characterized by strong breezes blowing constantly from the southeast. It is relatively cool and tends to be the drier of the two seasons. The monsoon season is characterized by unstable weather. Blazing sun is interspersed with torrential rains, and extended periods of calm are interrupted by violent storms.

The island is approximately three miles from northeast to southwest and 1.5 miles from southeast to northwest. It is of volcanic origin and rises to a maximum altitude of about 1,200 feet. Tikopia’s nearest neighbor is Anuta, 70 miles to the northeast, which it resembles in language and culture. To the west, its nearest neighbors are the Melanesian islands of Vanikoro, Utupua, and Ndenö, the Polynesian island of Taumako, and the Reef Islands with their mixture of Polynesian and non-Austronesian speakers. Tikopia’s population at the time of Firth’s initial study was around 1,270. Owing to substantial out-migration since the 1950s, the current resident population is only slightly larger, but there are now large Tikopian settlements on Vanikoro, Makira, Guadalcanal, and in the Russell Islands.

Prehistory

According to oral traditions, Tikopia was pulled up from the ocean floor by the demigod Metikitiki. The original occupants, the Atua i Raropuka (the Deity of Raropuka) and the Atua Fafine (the Female Deity), introduced the prototypical male and female economic activities: preparing sennit cord and plaiting pandanus-leaf mats. Several of the current descent lines claim autochthonous origin; others are said to have arrived from such diverse locales as Tonga, Pukapuka, Samoa, 'Uvea, Rotuma, Ontong Java, Motulava, and Anuta. Tikopians speak a Nuclear Polynesian language, related to Samoan and Tuvaluan.

Kirch's archaeological investigations indicate a period of continuous habitation spanning almost three thousand years, with tenuous suggestions of sporadic visits dating back close to another thousand. Kirch and Yen divide the island's cultural history into four periods, each typified by a distinctive artifactual assemblage. The earliest, which they term the "Kiki Phase," is characterized by Lapitoid ceramic ware, and it lasted from about 900 to 100 BC. The Kiki Phase gave way rather abruptly to the "Sinapupu Phase," characterized by incised Mangaasi-style pottery, apparently imported from northern Vanuatu. The Sinapupu Phase lasted to perhaps the 15th century AD and gradually gave way to the "Tuakamali Phase." The latter period is distinguished by a characteristically Polynesian artifactual assemblage and complete disappearance of ceramic ware. European contact began with Quiros's visit in AD 1606. Kirch and Yen use AD 1800 as the date marking the end of the Tuakamali and the inception of the "Historic Phase."

Over the period of human habitation, the natural environment evolved along with the cultural. Erosion was offset by shoreline aggradation, encouraged by a growing emphasis on arboriculture featuring *Calophyllum*, coconut, and *Antiaris* (the local bark-cloth tree). As a result, Tikopia's land area has increased substantially over the past three millennia, with a corresponding reduction of the fringing reef. During the Tuakamali Phase, an open saltwater bay was transformed into a brackish lake. As early as the Kiki Phase, marine life and avifauna became less abundant, and wild animal protein was supplemented with domestic pig. Pig husbandry flourished briefly but was abandoned late in the Sinapupu Phase.

Through the entire sequence, contact with the isles of northern Vanuatu, Santa Cruz, and west Polynesia attests to a complexity belying the apparent isolation of this tiny dot of land amid the vast Pacific Ocean.

Economy

As a high volcanic island, Tikopia includes a variety of ecological zones and offers an assortment of foods. For centuries, the most important crops have included coconut, taro, breadfruit, and yam. Today manioc, papaya, and several varieties of banana have been added to the island's list of staples. Other fruits and nuts include the Polynesian chestnut, *Canarium* almond, *Burckella obovata*, Malay apple, watermelon, and edible pandanus. Tobacco has become a major nonfood crop. Betel—a mixture of slaked lime, the leaf or stem of a pepper plant, and the nut of the areca palm—is a popular intoxicant. Turmeric is grown and valued as a ritually charged pigment and a flavoring for foods.

Domestic pigs have been only a minor source of nutriment. Animal protein is more commonly supplied by wild birds, domestic chickens, and, especially, seafood. Although Tikopia has no lagoon, it does enjoy a fairly extensive fringing reef, providing shellfish and assorted small reef fish. The island is large enough to offer calm seas on the lee side, enabling men to fish from small canoes using a number of techniques. The brackish lake provides a variety of resources rarely encountered on an island of Tikopia's size.

While some foods are eaten raw, the most esteemed are cooked, either over an open fire or in an earth oven. The most appreciated of these are "puddings" made by mixing a starchy vegetable such as manioc or taro with rich, white cream expressed from the grated meat of mature coconuts.

Most houses even today are constructed from logs and thatched with sago and coconut leaves. They are built directly on the ground on or near the beach. Roofs are steeply pitched, and doors are only two to three feet high. The sandy floor is covered with coconut-leaf mats, and one typically crawls about on hands and knees while inside.

Social Organization

Tikopia is divided into two geographical districts, known as Ravenga in the east and Faea in the west. Within each district are a number of villages (*pōtu*).

In addition, the population is divided into four patrilineal descent groups called *kainanga*, which Firth originally glossed as “ramages” and later termed “clans.” The *kainanga* are ranked and named; in descending order they are the Kainanga i Kāfika, the Kainanga i Tafua, the Kainanga i Taumako, and the Kainanga i Fangarere. Kainanga are nonexogamous, and they are geographically dispersed. They are led by chiefs (*ariki*), known as the Ariki Kāfika, Ariki Tafua, Ariki Taumako, and Ariki Fangarere. The chief is the senior male of his clan; other people are ranked in terms of genealogical seniority and their proximity to or distance from the chiefly line. An *ariki* is normally succeeded by his eldest son.

Since the *kainanga* are territorially dispersed, a chief may not be physically surrounded by members of his own clan. One chief, the Ariki Tafua, traditionally resides in Faea, whose population is made up predominantly of his clansfolk, while the other three chiefs traditionally reside in Ravenga. A Tikopian is expected to respect and obey all four chiefs and not only the leader of his or her clan. When important decisions must be made that bear on the community at large, the four chiefs consult. They usually make decisions by consensus.

Below the chiefs in rank are their close male relatives. These men are termed *maru*, and they serve—to use Firth’s expression—as a chief’s “executive officials.” A *maru* advises his chief on matters of concern to the community, transmits the chief’s decisions to the rest of the population, and makes sure the chief is kept informed of popular reaction to his dicta.

Each *kainanga* is made up of several *paito*. The word normally means “house,” but in relation to descent Firth characterizes the *paito* as “patrilineal lineages.” Members of a *paito* share in ownership of gardens (*vao*), orchards (*tofi*), houses, house sites, and canoes. A *paito* normally makes decisions about what crops are to be planted in which garden, when they are to be harvested, and how the foods are to be prepared, and it allocates labor for completion of the various tasks. A chief may override a *paito*’s rights of ownership under certain limited circumstances, and he may even confiscate land or—in earlier times—punish an offender by exiling him to the ocean, a penalty considered tantamount to execution.

Virtually all of Tikopia’s land is owned by one or another lineage, and it is under constant cultivation. Tikopians practice a form of crop rotation, but rarely is a plot permitted to lie fallow. Any garden that is not

in active use may be temporarily cultivated by another lineage. A lineage that plants on another’s land must compensate the owners by sharing a portion of the harvest. After a successful harvest, ceremonial first fruits payments traditionally were made to the chiefs. Today, such payments are likely to be offered to the church.

Kinship

Kinship terminology in the parents’ generation is of an Iroquois type: the father and father’s brother are both called *tamana* or *mmana*; mother and mother’s sister are *tinana* or *nana*; the father’s sister is *masikitanga*, and mother’s brother is *tuatina*. In ego’s generation, kinship terminology approximates a Hawaiian system: all cousins of the same sex as ego are called *taina*, while those of opposite sex are *kave*. Unlike most of Polynesia, Tikopians do not distinguish terminologically between older and younger same-sex siblings. A man calls his own and his brothers’ children *tama*, while he calls his sister’s children *irāmutu*. A woman calls all her siblings’ children by the same term that she uses for her own: *tama*. Grandparents and ancestors are all called *puna* or *tupuna*, while grandchildren and descendants are all *makopuna*. In the affinal system, “husband” is *matua*, “wife” is *nofine*, a sibling-in-law of same sex as ego is *mā*, and a sibling-in-law of opposite sex is *taina*. Parents-in-law call children-in-law *fongōna* and are, in turn, called *fongovai*.

The interactional tone of kin relationships varies as significantly as terminology. Children treat their fathers with respect. One follows one’s father’s instructions; refrains from uttering the father’s name; abstains from rough joking, practical joking, or conversation about sex; steps aside when meeting the father on a path; and avoids turning one’s back on the father. Like the father, the mother is treated with respect, but the relationship is also characterized by unambiguous affection and a degree of freedom. The mother’s brother and sister’s child treat each other with easygoing warmth; they joke with one another and may discuss romantic concerns. The father’s sister is treated with respect and is thought of, in certain respects, as a female father. The grandparent-grandchild relationship is warm and supportive.

Siblings of the same sex are expected to share relations of solidarity. They may tease each other and confide in one another about sexual affairs. If a question of ritual honor or political authority should arise

between same-sex siblings, the younger sibling normally defers to the elder, but under most circumstances, they refrain from using formal markers of respect.

Relations among siblings of opposite sex also tend to be friendly and relaxed. They respect one another, but the extreme brother-sister avoidance found in much of west Polynesia and some of the Polynesian outliers is absent on Tikopia. Brothers are expected to look after their sisters' interests, but they are not pre-occupied with protecting their sisters' virtue as has been reported, for example, in Samoa. Indeed, Firth notes that a brother and sister may spend time together in the same house without a third party present to chaperone, and they are even permitted to sleep on the same mat, under the same covers. However, unlike Hawai'i, where a man of high rank might marry his sister, sexual relations between siblings or close cousins on Tikopia would be regarded as incestuous.

The relationship between a husband and wife is expected to be close and informal, although differences in rank, should they become relevant, favor the husband. In general, in-laws of adjacent generation and siblings-in-law of the same sex treat one another with extreme respect. One does not use the other's proper name and does not stand while the other is seated in his presence. They do not turn their backs on one another, do not tease each other, avoid discussing subjects relating to sex, and do not raise their voices near each other's homes. In speaking to each other, they express respect by using the dual form of the personal pronoun—a word that means “the two of you.” Siblings-in-law of opposite sex are called by the same term (*taina*) as siblings of same sex and, like siblings, are expected to have a warm, close, informal relationship. They may talk about romance, may joke sexually, and are appropriate marriage partners.

Gender

Tikopia has a fairly clear gender-based division of labor. Men build houses and canoes, and they do most of the fishing beyond the fringing reef. Women devote a larger proportion of their time than men to child care. They prepare bark cloth for sheets and clothing, and they plait mats. Older children care for younger siblings, but girls play a more active role than boys in that regard. Both men and women work in gardens, but men are more likely to clear the brush,

while women devote a somewhat greater proportion of their time to weeding, mulching, harvesting, and food preparation. Both men and women collect seafood on the fringing reef, but men are more likely to spear fish while women devote more of their time to combing the reef for shellfish.

Men tend to be politically and ritually dominant. Only men are chiefs and *maru*. Within the house, the highest-ranking male sits in the most ritually prominent spot. In decision making, a wife is supposed to defer to her husband's judgment. In church, only men are priests or catechists. And congregations are segregated according to gender, with men sitting on the ritually superior right side while women sit on the left. However, Tikopians say that men should treat women with respect, and they even say that a married woman is *tapu*—“sacred.” A good husband considers his wife's feelings and takes her judgment into account when making decisions. A man treats his father's sister with the utmost respect and has a close, affectionate relationship with his mother.

Relations between boys and girls are generally relaxed, and differences in rank are not marked. Girls and boys might play together when very young. As teenagers they meet at dances, which occur on ceremonial occasions as well as more casually on the beach on moonlit nights. Firth reports that in pre-Christian times men of high rank practiced a kind of ritual marriage by capture. That, however, ended with establishment of the church.

Religion

The traditional Tikopia religion recognized several kinds of spiritual being. The generic term for spirit is *atua*. Some of these were ghosts of deceased neighbors or kin. Others were believed never to have been human. Powerful gods of nonhuman origin were called *tupua*. The great pan-Polynesian deities, known by such names as Tu, Tane, Rongo, and Tangaroa, were recognized on Tikopia but assumed less prominence there than in the major archipelagoes. The most important gods were spirits of deceased chiefs; paramount among them was the Atua i Kāfika, an ancestor of the premier chief, the Ariki Kāfika. During life, this man was an important cultural hero who introduced many elements of the island's historic social structure.

Central to Tikopian religion is the pan-Polynesian concept of *mana* or *manū*; Tikopians treat the two

words as synonymous. Firth translates *manū* as “power” or “efficacy.” Tikopians cite *manū* to explain unusual success or good fortune. A person who has (or is) *manū* can affect the weather, crop fertility, success or failure in military combat, and the health of those around him. Persons of high rank, particularly chiefs, are believed to possess an abundance of *manū* and are expected to use it to ensure the community’s well-being. Tikopian religion, as is true in much of Polynesia, was concerned more with assuring economic security for the living than with questions of abstract morality or rewards after death. Possession of *manū* is associated with genealogical seniority and direct descent from the most powerful gods.

As in much of Polynesia, Tikopian chiefs (*ariki*) are not only political leaders but served in the old religion as high priests. They were responsible for communication with the most important spirits and led the community in worship activities. Tikopia’s most important worship activity involved an elaborate semiannual ceremony known as *te fekau o nga atua*—“the work of the gods.” Worship ceremonies themselves were termed *fai kava*—“performing kava.” Kava (*Piper methysticum*) is a type of pepper plant, and it was the most widely used intoxicant in Polynesia prior to the introduction of alcohol. It remains a ceremonially important beverage on many islands. Tikopians, however, prefer to ingest betel and reserve kava for the gods. Certain ritual practitioners poured kava liquid onto the ground as an offering during worship ceremonies.

While chiefs were ultimately in charge of worship, their jobs were largely administrative. Much ritual performance was handled by *pure* or *matāpure*, a term that Firth glosses as “ritual elder.” *Matāpure* were the leaders of religiously important lineages, and their ceremonial role could be as prominent as that of the chiefs themselves. *Maru*—“executive officials”—might also assist the chiefs in carrying out religious activities, but their major responsibilities were in the mundane realm.

In addition to chiefs and ritual elders, whose functions could be described as “priestly,” Tikopia recognized spirit mediums (*vakaatua*, literally “spirit vessel”) who communicated with spiritual beings by going into trance states. A medium would be possessed by spirit familiars who spoke to the community through the *vakaatua*’s mouth. Tikopians often depended on spirit mediums to explain misfortune,

to discern the fate of kinsfolk lost at sea, and to answer a variety of other perplexing or disturbing questions. Mediums might be either male or female and of any social rank.

Attempts to convert Tikopia to Christianity began in the 19th century but met with little success until the 1920s when Ellison Tergatok, an Anglican mission teacher from Vanuatu, settled on the island. Tergatok, who later was ordained as an Anglican priest, convinced the Ariki Tafua, Tikopia’s second-ranking chief, to convert, and when he did, virtually the entire Faea district—where the Ariki Tafua made his abode—converted with him. Still, at the time of Firth’s initial field study, approximately half of Tikopia’s population, including three of the four chiefs, continued to practice the traditional religion.

The ensuing two and a half decades witnessed an ongoing rivalry between the island’s Christian and pagan communities, with the Christians slowly but inexorably winning converts. Finally, during the early 1950s, Tikopia was struck by a powerful hurricane, followed by a drought and famine, and finally an epidemic that decimated the already-weakened population. Islanders perceived that pagans suffered more than Christians from these natural disasters, and they took that as a divine message. As a result, the last of the chiefs converted to Christianity and, with him, the remaining holdouts among the general population entered the fold.

At the start of the 21st century, Tikopia is a thriving devoutly Christian Polynesian community, and Tikopians have achieved a level of national prominence in the mostly Melanesian Solomon Islands that far exceeds their numbers in the population. Almost all Tikopians continue to be loyal Anglicans. Several have been ordained as priests, and two have served as bishops. A number of Tikopians have taken prominent positions in the civil service at the national and provincial levels. Particularly noteworthy was Sir Fred Soaki (Pa Nukuriaki), a long-time commissioner of the Royal Solomon Islands Police. On February 10, 2003, Sir Fred was assassinated while working to resolve an inter-island conflict that had torn apart the country over the previous four years. That, however, is another story.

The many differences between the ways time is understood in different cultures, as well as the ways in which such differences might affect those cultures, can be divided into three main areas: what time is, how time is experienced, and how it is measured—the metaphysics of time, the perception of time, and the metric of time.

The Metaphysics of Time

The term *time* can be used to refer to a number of different, though connected, concepts. The concept of change is a central one; one often refers to time when, in fact, one is thinking of the events occurring within time. This is most obvious with regard to utterances such as, “Time is the great healer,” or *tempus edax rerum* (time the devourer of things). Strictly speaking, time has no causal powers, either of healing or of destroying; what a speaker is really referring to in such cases is the succession of causally related events whose occurrence is noted as the passing of time. Whether time is something in itself, rather than merely the relationship between events, is one of the main questions dealt with in the metaphysics of time.

Questions about the reality, the nature, the shape, and the origins of time are often bound up with more general cosmological theories. Such questions

include: Did time have a beginning? Is time linear or looped? Is time real? Is time something in itself, over and above the events that occur within it? Generally, cultures only develop answers to questions of this sort when the questions have been asked, which usually involves the development of a philosophical tradition. As with the perception of time, many writers try to develop a metaphysical theory of time from the literature and languages of cultures that have produced no explicit, worked-out theory of time; they face the problems described below.

The Perception of Time

The phenomenon of subjective time perception is familiar: At its simplest, when one is engaged in pleasurable activities or is concentrating, time can seem to speed by, but when one is bored or waiting for something, time seems to drag: “Time flies when you’re enjoying yourself,” and “A watched pot never boils.” Other factors relevant to perceptions of time may be age (time seems to pass more quickly the older one gets), the season, the weather, the time of day, and so on. It has been argued that these and similar factors lead to a larger-scale cultural phenomenon: that members of different cultures experience time differently.

Since it is impossible to directly compare the experiences of two people, evidence for such theories must be circumstantial; much reliance is placed upon the linguistic patterns—and especially the writings—of the cultures being compared. Two major problems face the researcher. First, it’s important to distinguish between the way someone experiences the world and the theories of the world that person develops. For example, I believe that an oar remains straight when dipped into water, but I still see it as bent; however strong my belief that the oar doesn’t bend, I can’t see it as straight. In the same way, many cultures have developed the theory that time is cyclic, but no one has ever *perceived* time as cyclic. The way that time is talked and theorized about need not reflect the way that it is experienced.

Second, unless one already understands how a culture experiences the world, it’s extremely difficult to understand or even to recognize that culture’s use of metaphor and other indirect uses of language. Imagine trying to construct an account of how English speakers understand the nature of mind or experience mental phenomena on the basis of such

expressions as: “I’m of two minds about that,” “He’s lost his mind,” “It’s got a mind of its own,” and “She can’t make up her mind.”

The Metric of Time

All human societies have developed systems of measuring time based on regularities in the natural world—usually using astronomical phenomena such as movement of the sun, phases of the moon, changing positions of other heavenly bodies (either directly or via the seasons), tides, migrations of animals and birds, etc. Aside from the fact that these regularities are easily observable, they were also linked with activities such as agriculture, hunting, and travel, and religious ritual.

The ability accurately to measure time both affects and is affected by societies; for example, although the Chinese developed clocks long before the Europeans (as evidenced by the Chinese mechanisms taken to Europe and used in the development of clocks there), the Chinese didn’t manufacture or use them except as novelties. In Europe, on the other hand, the clock was seen as the symbol of scientific advancement and rapidly became ubiquitous in private houses and in public places. The measurement of time became the center of European social and commercial life, creating the structure of lives both at work and at play. Thus one distinction that might be drawn between different types of culture is that between those cultures whose experience of time is in terms of certain natural cycles (day and night, phases of the moon, some pattern of seasons, and the year) and those cultures that have developed measurement in such a way that their experience of time is in terms of a succession of more-or-less regular units such as hours, days, weeks, and months.

Often, however, the two ways of experiencing and/or of measuring time sit side by side in different aspects of a culture—evidenced most commonly in secular and religious aspects. For example, secular Western societies count days as twenty-four-hour periods running from midnight to midnight, relying on the solar calendar for most time keeping; for religious purposes, on the other hand, sunrise and sunset are still used to mark the bounds of the day, and the lunar calendar remains important for calculating certain feast and fast days.

TIME IN ANTHROPOLOGY

The nature of time is a topic of commanding interest to scholars in many different academic disciplines. Anthropology has been concerned with time in two major ways. The first is how human beings create and express time, including the generic, universal, homogenous time of science that many people take for granted. The second concern is the issue of representations of temporality, particularly in the anthropologist’s ethnography, and how such representations “freeze” cultures in an effectively timeless or eternal state.

The Past

The legacy of modernism in the anthropological study of time is the challenge to the singular nature of time. By the late 1800s, a centuries-old opinion had begun to settle in as received wisdom; namely, that time was a uniform and universal yardstick of human existence and experience. Newtonian time was assumed to hold everywhere; Kantian time, while individually experienced, was a unitary phenomenon. Time tended to be conceived as a public, universal phenomenon.

In the late 19th and early 20th century, the universalist tendency came under closer scrutiny. Newly formed social science disciplines, such as psychology and sociology/anthropology, undertook studies of

time. The result was a growing sense that far from being public and universal, time and the experience of it was private and somewhat idiosyncratic. By the 1910s, a growing number of scholars came to believe that time was far from universal.

Several scholars figured prominently in the reformulation of time as privately held. Henri Bergson's writings on duration helped ground time conceptually in the perception of the temporal subject. Bergson's notion of *durée* was an expression of the flow of consciousness. And William James's now famous neologism "stream of consciousness" was itself an attack on those who would divide temporal consciousness into discrete units—as he said, like describing a river in terms of bucketfuls of water.

The Present

Émile Durkheim and his followers investigated temporality from an analytic and theoretical stance midway between public and private, shared and idiosyncratic. Durkheim, Marcel Mauss, and Henri Hubert conceived of time as variable across social groups—variably perceived, variably expressed. But they also considered time a shared phenomenon in its cultural expression. Hence a midpoint between the public and the private—time may be individually expressed and experienced, but it is at heart a social construction, a product of the social group, and must therefore be public and shared but variable across different social groups.

Most of the early work of these scholars involved sketching this position theoretically. The empirical investigations tended to center on calendars and the rhythmicization of time. That is, what are public expressions of time, and what social work do they accomplish? Calendars are an obvious answer, and Hubert's now-famous work on the representation of time examines how time is constructed calendrically. Part of the thrust of Hubert's argument is that time is a necessary component of magical and religious representations. The work of the calendar is not to measure time in the sense of giving magical or religious acts a fixed date, but to give tempo or rhythm to time, to regulate the intervals of the sacred and the profane.

E. E. Evans-Pritchard, Claude Lévi-Strauss, and Edmund Leach are all intellectually descended from Durkheim's structural position. Leach takes Durkheim and Hubert's argument to its logical conclusion in suggesting that time is nothing more than the alternation

between the sacred and the profane. Leach's argument is succinct and well stated, if somewhat extreme. Leach seems to confuse the discursive, symbolic manipulation of time and the reality of time. That is, in a fit of Durkheimian exuberance he mistakes oscillations in temporality for oscillations in time. Thus ritual action does not actually, as Leach might claim, cause time to run backward, although it can cause a symbolic, temporal reversal that is as powerful as reality.

Evans-Pritchard specifically interrogates time and space in his monograph *The Nuer*. He argues that both are products of social groups and structural principles. In so doing, he suggests there are two types of times, ecological and structural. Ecological time is physical and pertains to the environment. Structural time refers to kinship and other social structures, and hence the social distance between elements of social structure. Evans-Pritchard makes the point that both are structured by activities. So, despite the seeming tangibility of a calendar, it is really religious, social acts that constitute time. Where Evans-Pritchard's argument is the weakest is his discussion of what Nuer must feel about time, even though they have no word that overlaps with our word "time." He argues that time must therefore be felt in a different, perhaps less hurried, way. It is altogether unclear where his evidence for this lies, since he offers no further explanation, although the thrust of the argument is similar to that of the Linguistic Relativity Hypothesis.

Evans-Pritchard and Meyer Fortes in their monograph *African Political Systems*, and Fortes alone in his *Structure of Unilineal Descent Groups*, interrogate the relationship between descent reckoning and social time. The concepts of age sets and especially of age grades elaborated by descent theorists paint a picture of the social time of the group mediated by socially defined age categories. Time is literally based on the (aging) trajectory of the social body. This view of lived social time is often overlooked but is deeply relevant to any study of the anthropology of time because of its cross-cultural pervasiveness.

The structuralism of Lévi-Strauss rarely addresses time explicitly, as one might expect from such a static theory. The essential temporal criterion in classifying societies is group awareness of their history. "Hot" societies were aware of their history, whereas "cold" societies tended to view historical pressures as coming

from outside the society. This understanding perpetuates the idea of timeless, primitive groups, which has not been an accurate model. Even diachrony for Lévi-Strauss is merely a different kind of structure, a multiplication of synchrony. Lévi-Strauss represents the other side of Durkheimian thinking from Leach. Whereas Leach had argued explicitly for a theory of time, Lévi-Strauss addressed himself primarily to issues of synchronic structure.

Clifford Geertz has argued that Balinese culture attempts to detemporalize time. In "Person, Time, and Conduct in Bali," Geertz explains his model of Balinese lived social time, based on groups of predecessors, contemporaries, consociates, and successors. His argument, that Balinese prefer to make fellowmen from contemporaries as much as possible, is reinforced by his interpretation of Balinese time. However, there is some slipperiness to Geertz's definition of time, for it is both the experience of time that he addresses and, elsewhere, it is the conception of temporal order. Geertz does not make explicitly clear what he thinks time is, or rather, what he thinks he is analyzing when he refers to time.

There has been some scholarly attention to the problem of conceptions of time, that is, what people *think* time is, as opposed to what they *say* time is. At the root of analysis of categories of thought is the Linguistic Relativity Hypothesis, also known as the Sapir-Whorf hypothesis (so named after its originators, Edward Sapir and Benjamin Whorf). The argument that because of grammatical facts about the Hopi language, Hopi individuals experience time not in quantifiable units (as speakers of English do) but in terms of general cycles has been provocative in fields within and outside of anthropology. The problems of Hopi conceptions of time, and the argument that one's reality is indeed affected by language structure and use, directs one to concentrate on how time is perceived—a problematic but worthy endeavor for the anthropologist, who typically studies what is said and done, not thought. Gathering nonlinguistic time data is certainly a challenge and tends to fall outside the purview of anthropology as well.

Currently one sees in anthropology increased attention given to dynamic tensions between individuals and structures, between patterned and novel activity. In this regard, practice theory holds important implications for the study of time. The theorists of structure and practice, of which Pierre Bourdieu and Anthony Giddens are exemplary, are interested in

temporality to the extent that individual actors create their worlds with it. Thus, for Bourdieu, the time of prestation to counterprestation helps expose a wealth of cultural knowledge to the anthropologist. The tactical gift giver uses the tempo of gifting to make his prestation seem neither formulaic nor tardy. Time, in this model, is to be manipulated, or put more precisely, is the outcome of intentional, timed, acts.

In *The Fame of Gawa*, Nancy Munn argues persuasively for an ethnographically grounded, symbolic, and practice-centered approach to understanding the creation of symbolic value in a Massim society. The aspect of Munn's approach of particular relevance to the study of time is her investigation of the structuring of lived time, of the tempo of different kinds of prestation, from the reciprocal giving of food to the asymmetrical (nonreciprocal) *pokala* exchange. Elsewhere Munn has further developed these ideas of emergent spacetime (space and time are fundamentally, complementarily linked for Munn, and not oppositional categories) and has called for more research into how time is made local and valuable. The implications of this approach, and they seem quite reasonable, are that time is constantly (re)produced in everyday practice according to larger sociocultural structures.

Time is produced in ethnographic writing as well. Johannes Fabian suggests that temporality is smuggled in by certain ways of knowing and writing. Thus classic anthropological accounts tend to ignore time in favor of spatial analyses, with a timeless, "ethnographic present" the result. Fabian's is a reflexive approach that understands temporal operations to be at the heart of anthropology making its Other.

It is also true, following Fabian and others, that removal in space also indexes removal in time, of placement backward in time. In other words, tribal groups living far away from the metropole are assumed to live not just at a remove in space but in time as well. Hence the diorama view of culture, of the eternal present of primitive communities as depicted by so many anthropologists. Fabian, George Marcus, Michael Fisher, and others draw critical attention to the concept of time in (writing) anthropology.

The Future

The anthropology of time must work to resolve three major issues in the future. Certainly one issue is to

find a meta-language for time. And as philosophers at least since Immanuel Kant have observed, time inheres in all categories, making it exceptionally hard to distill for analysis. So isolating the problems and creating the vocabulary to talk about the problems will be the first set of issues.

The second set of issues will revolve around modeling time in a way that is simpler than reality but still does justice to reality. This may not be as difficult as it sounds. We know time is an aspect of all categories of knowledge. Part of this must be to do with language, or at least those languages which require a temporal argument to be made at each utterance. Thus far, insufficient attention has been paid to temporal coding in language, to what must be said about event order relations and what effect, if any, this would have on cultural concepts of temporality. But not just language—the temporal effects of other basic cultural regimes must be understood before the larger workings of time in culture can be clear. To this end, we must take to heart the critique of the time of anthropology. Indeed most disciplines have a particular time frame which guides analysis, and it must be made explicit at the outset of any study of the cultural temporality.

We also know that temporal regimes, like cultural ones, are shared. In fact, they must be shared in order to accomplish their main task of synchronizing the otherwise idiosyncratic behavior of individuals. The issue of synchronizing then leads us to the final set of issues. How do these beliefs become shared, and to what extent are they shared? How and why do some people choose to ignore common temporal regimes, such as Daylight Saving Time? These processes of selection and synchronization all engage temporality as part of the exercise of power.

TIWANAKU (TIAHUANACO)

Tiwanaku (also called Tiahuanaco) was a state-level society centered in the southern Lake Titicaca Basin of South America. The exact dates for this civilization are an issue of contention, but most archaeologists agree that the peak of Tiwanaku cultural expansion occurred between the 8th and 10th centuries AD. The civilization saw considerable change, including a breakdown of centralized political control, after about AD 1000. The capital site of Tiwanaku was mentioned in versions of Inca tradition as the place where the world was created, the original home of the Inca lords, and the birthplace of Inca kings, and the site was in continual use through Spanish colonial times.

The capital and type-site for the Tiwanaku culture is located roughly 20 kilometers from the southern end of Lake Titicaca and 72 kilometers from La Paz, Bolivia. The site is best known for a series of large temple structures resembling large, artificial hills. Colonial Spanish observations and 20th-century archaeological investigations revealed temple architecture to consist of compacted earth held in place by cut stone blocks of red sandstone or dark gray basalt. Monumental gateways, such as the Gateway of the Sun, were intended as part of the latter phases of construction. The site has also revealed the presence of substantial monolithic statues, semi-subterranean courtyards, and the practice of human sacrifice.

It is estimated that the city's population reached 250,000 at its height. People of the city obtained needed resources from a vast complex of raised-field agriculture extended throughout the Lake Titicaca Basin as well as long-distance caravan trade networks reaching from the Atacama Desert in the south to the Moquegua Valley in the north. Available data suggest that Tiwanaku developed an economic system that included distant colonies of *altiplano* people as well as trade relations with people who were influenced by, but not fully incorporated into, the Tiwanaku culture. This long-distance trade, in addition to religious pilgrimage, may also have been what fostered the initial growth of Tiwanaku.

Secondary sites in neighboring valleys include multiple-component residential and administrative complexes at Khonko Wankane and Lukurmata. Large Tiwanaku sites such as these characteristically display artificial mounds, sunken rectangular courtyards, and

open plazas in addition to domestic architecture of mud brick and assemblages of characteristic artifacts. Most recognizable among the artifacts are a tall flared cup, or *kero*, and a short flared bowl, or *tazon*, used for serving corn-based beer and a stew of meat and potato.

Tiwanaku social organization, architectural forms, and religion drew heavily upon earlier cultures in the Andean highland area known as the *altiplano*. The *Yaya-mama* (literally “man-woman”) religious tradition is thought to have been a unifying force across cultural complexes as well as a strong influence on religion in Tiwanaku. The iconography of this religion shows strong male–female dualism in conjunction with felines, camelids, toads, snakes, and mythical creatures, many of which find their way into Tiwanaku iconography. Like many in the Andes, Tiwanaku people practiced several forms of cranial modification and buried their dead in a flexed seated position.

The Tlingit are a people who are part of the Na-Dene phyla, and reside in the southeast Alaska panhandle and inland Canada. They are a matriarchal society, receiving their lineage of crests from their mothers' clans. From time immemorial they have been a powerful people living on the edges of the boreal forests, using cedar as their medium for longhouses, canoes, utensils, and clothing. They are known for their potlatches and were fierce warriors. Their subsistence was derived mainly from the ocean: salmon, halibut, seal, shellfish, and seaweed. With the introduction of Europeans (first Russians, then Americans) to the

Chilkat Blanket, circa 1870–1880

Tlingit homeland, many confrontations, challenges, and changes took place among the Tlingit people. Diseases such as smallpox and the measles were new to the Tlingits, and the ravages of these illnesses nearly eradicated entire villages. Totem poles and other artifacts were either taken or burned, English was enforced, corporal punishment was administered for speaking Tlingit, and the potlatch was forbidden. Today the Tlingit are a modern people who are politically strong, and who are embracing their culture once again.

Lifestyles

In times of antiquity, the Tlingit were a dominant people known for their warriors who wore wooden helmets and leather tunics or wooden slat armor; for their longhouses made from thick planks of cedar and carved house posts and screens, which housed several families and slaves; for the totem poles carved with the details of ancestral lineage and natural and supernatural beings; for the canoes, especially the huge war canoes with elaborate clan carvings; for the potlatches that would last for about a week; and for the woven Raven's Tail and Chilkat blankets (later button blankets). These were mostly a seminomadic people who had their winter homes where their longhouses and totems were situated. There were fishing camps, berry gathering areas, bird-egg islands and rookeries, and areas where the herring spawned, as well as camp areas made during hunting, trapping, and war, or

Pamela Rae Huteson wearing an eagle button blanket and spruce-root hat.

during trading times. Camp areas were owned by clans and individuals and were considered property to be distributed during potlatches.

The Tlingit are a matriarchal society, and claim their crests from their mother's moiety. The two main moieties are Crow/Raven and Wolf/Eagle; Crow and Wolf are from the inland Tlingits who are closer to the Athabascans; it may also be an earlier form of Raven and Eagle. Within these clans are subdivisions of various clans and houses. Marriages were arranged, and it was taboo to marry within your own clan, so care was taken to know the clans of the people. This clan knowledge was especially important when giving a potlatch.

A boy of 8 to 10 would be sent to his maternal grandfather or uncle to be trained until he reached manhood, not only as a hunter and fisherman, but also as a warrior. Girls lived in solitude for up to a year when they started their menses, during which

time they would learn to weave and perform other skills that would prepare them for womanhood.

The raising of the totem, which illustrated their lineage and legends, was part of the memorial potlatch ritual, as well as one of the ways a new keeper/owner/chief of the house would prove that he was worthy of the position. There were many reasons for a potlatch, but unlike the Kwakiutl who sought to "bury" their guests with their wealth in competitive potlatches, the Tlingits focused on the memorial, since a high-caste person could have several memorial potlatches. Events in a potlatch could include oratory of ancestry and the rights of connections to the supernatural, songs and dances, name giving, feasts, gambling, and destruction of property (for example, canoes, copper shields, or slaves).

When a person died the remains were cremated, along with articles that would assist his or her journey in the spirit world, such as clothing, weapons, and at times a canoe or slave. Food and water were also thrown into the fire, to ensure that the person would not be hungry or thirsty en route to "Raven's house." A shaman was embalmed and placed in a memorial house or on a platform built in a tree. Usually his shamanistic articles lay beside him, for example, specific ritual clothing, rattles, and carved spirit guards that had watched over him as he slept in life.

Salmon runs started in late spring and lasted until early fall; stone and stake weirs were set at the mouths of streams to catch returning salmon. Stakes dating over 1,350 years old have been found at the Klawock River. Salmon was mainstay of the Tlingit diet and was supplemented by halibut, seal, sea lion, shellfish, herring eggs, seagull eggs, deer, bear, and beached whales. A variety of berries were gathered in intricately woven spruce root baskets, then dried and pressed into cakes and packed into bentwood boxes for storing. Eulachon or "candlefish," commonly known as "ooligan," was processed to make the oil for food and trade. Stone tools were crafted for hammering stakes as well as stone weaponry and sacred items. Petroglyphs and carved rocks were made to show clan ownership and placed along the shoreline. There are also petroglyphs of sailing ships, from when the first Europeans arrived.

European Encounters

When smallpox and the measles spread from village to village after contact with Europeans, some villages were abandoned; those not sick buried their dead and

left their homes to regroup in nearby villages, in an attempt to maintain their lineages. This was a time when many of the old customs were modernized, for example, memorial poles were replaced with headstones and the accompanying potlatch was replaced with a lunch or dinner. Despite conversion to Christianity, however, *at.óow* (clan crest artifacts) were still burned after the death of one known to be high caste.

The aboriginal peoples of the northwest captured the imagination of Europeans as museums of natural history opened throughout America, and tribal information and artifacts were in high demand. This prompted many to write about the Tlingits and other First Peoples they had contact with, for example, George Thornton Emmons, who was on active duty with the Navy, and Salisbury, a principal of the Klawock School on Prince of Wales Island. Some writings from these amateur ethnographers prove to be windows into the past of the Tlingit; others, like Salisbury's *Quoth the Raven: A Little Journey into the Primitive*, also revealed the "white man's" mindset pertaining to the civilizing of the "savages." Throughout the northwest there were part-time "collectors" of Native American artifacts who were not above grave robbery. Louis Shotridge (Tlingit) was hired by the University of Pennsylvania's museum to obtain Tlingit tribal artifacts with documentation and provenance on each item. To this day he has been praised for the quality of the artifacts, and especially the thorough information on each article; he proved to be superior to any other ethnographer working among the Tlingit people. However, he also angered his fellow Tlingits, to the point where some would hide their artifacts when he came to town. Affluent businessmen from Seattle would take voyages to the "wilds" of Alaska or Canada to gather artifacts from seemingly abandoned villages. A case in point is the pilfered totem standing in Pioneer Square in Seattle, which was stolen from the winter house of Tongass while the residents were living at their fishing camp.

When the American saltries and canneries started appearing, the local Tlingit clans proclaimed their rights to fishing areas and imposed a fee, which for

about a decade some did honor and pay, but with the increase of fellow Americans, and as the military's presence became stronger, the claims were no longer honored. In 1899, Jefferson Moser, an agent of the U.S. fisheries, noted the confusion the "Indians" felt about the lack of honor concerning the refusal to pay tribute for the use of the Tlingit's fishing areas. The mid-1800s to early 1900s, when the missionaries and schoolteachers started arriving and the United States assumed ownership of Alaska, became a time of great change within the Tlingit tribes.

Present Day

In 1938 the Indian Civilian Conservation Corps (CCC), with the collaboration of the U.S. Forest

Service, employed Tlingit carvers from southeast Alaska to restore and re-carve the totems in an effort to preserve the cultural art and make them more accessible to the general public. Some of these carvers had once lived in the very abandoned villages from which these totems had been removed. Anthropologist Viola E. Garfield researched and documented the stories of these totems and presented her findings in *Wolf and the Raven*. The craft of totem carving was thought to have been a thing of the past; the CCC project, however, did much to revive and stimu-

late the skills as part of a series of events of cultural restoration. Also, Bill Holm recreated the form-line art design system traditionally followed by the Tlingit, Haida, Tsimshian, and Bella Bella that had almost been lost due to the various forces of acculturation working against the traditional clan artists. Holm's *Northwest Coast Indian Art: An Analysis of Form* created a revival in Northwest Coast art among the Tlingit artists, and serves as a part of many a new carver's curriculum. In 1976, when the Klukwan Frog House artifacts were sold, Klukwan's leaders created a law forbidding the sale of Klukwan artifacts.

There have also been unsettling events, such as the burning of regalia in 1992 when a Tlingit Evangelist, Flo Ellers, challenged a congregation as to what is not permissible for a Christian by stating, "There will be no Chilkat dancers dancing in Heaven."

In 1994, an unprecedented event attracted international attention when a judge in Everett, Washington released two teenage Tlingit boys to the Combined Tribal Court of Thlingit Law. The Tribal Court sentenced the boys to banishment, which had not taken place in over one hundred years. This caused a division among the Tlingit people: some said "there never was such a thing," while others rejected the leader of the project, and therefore rejected the banishment. However, many of the younger generation recognized it as a step toward sovereignty. One of the boys later stated, "There was nothing negative about

my banishment. It was a time for self-respect, introspection, and purification. It helped me get back to my roots."

Since the first contact with Europeans, the Tlingit have adapted and adopted a new way of life. Their Tlingit culture, once denied them, is now being embraced; potlatches are being held; Tlingit art is flourishing; the sound of the adze is heard throughout the land; carvers are creating heraldic clan totems; tribal justice is taking its rightful place for the people; the language is being taught; and Tlingit clan conferences are being held to assist the people in making connections to their tribal past. There is also an increase in the number of Tlingit politicians, anthropologists, lawyers, and scholars. In ancient times, Raven taught the Tlingits, "the people," to adapt to change, a lesson that the Tlingits have learned well.

TLINGIT CULTURE

The name Tlingit means *in the people*. These Native Americans continue to inhabit many of their aboriginal village sites along the southeastern coast of Alaska. Foraging people, they were well adapted to hunting and gathering in rugged temperate rain forest and at sea. Tlingit came to depend on income from fur trapping and an active arts and crafts trade. Today they value education and work in business, industry, government, and professions.

Their kinship system was matrilineal, as in the Haida and Tsimshian tribes. Family name and inheritance, as well as rights to property and privileges, including resource sites and ceremonial activities, were passed down through the mother's side of the family. Each person belonged from birth to either the Eagle or the Raven group and was permitted to marry only a person from the other group. Ravens and Eagles were divided into clans, each with its own animal symbol or crest, and clans were further divided into houses or extended families.

Traditional religion was based on the animistic belief that spirits called *jek* inhabited people, animals, and objects in the natural world. The environment could be influenced, for good or ill, by human intervention, and that made it important to observe customs that ensured prosperity by placating the souls of animals hunted. The Tlingit also believed in a creator whose name had to be whispered. All members of the tribe were reborn from one of their ancestors, and the ancestors were included as elements of their totem pole designs. A shaman acted as priest, doctor, or counselor. When hundreds died of tuberculosis in the early 20th century, people lost faith in shamans and turned to Christianity for comfort. Russian Orthodox and Presbyterian

missionaries made significant impact on the Tlingit. Many gave up their Tlingit names, from which they had derived identity and status, and were given new names when they became Christians.

Contact with Europeans began with explorations in the 18th century. After brief encounters with Russians and Spanish at the beginning of the century, the Spanish set up business at Nootka Sound in 1789, the Russians at Sitka in 1799; British trading companies became well established early in the 19th century. Tlingits suffered from disease and alcohol introduced by Europeans; hundreds died between 1836 and 1840.

Just when Tlingit culture was most vulnerable, European settlers began to arrive. Americans came looking for gold and began to occupy and control Tlingit lands. The U.S. purchase of Alaska from Russia in 1867 brought even more settlers to establish canneries, mines, and logging camps, challenging the Tlingit tradition of taking only resources needed for survival. American military strength silenced Tlingit protest. In 1912, Tlingits joined with other tribes and founded the Alaska Native Brotherhood (ANB) in an attempt to fight for their civil rights and subsistence sources. In 1929, Tlingits initiated a struggle to regain control of their natural resources that led to the Alaska Native Claims Settlement Act of 1971 and the return of millions of acres of land.

There has been a revival of interest in Tlingit dances, songs, language, artwork, stories, and potlatch gatherings. The fight for survival of a culture continues. Tlingit ability to live off the land and sea is continually at risk due to logging, overharvesting of fish by commercial fisheries, increasing population, and government regulation, but Tlingits are politically active on local and national levels and remain focused on land and resource claims, self-rule, and cultural resource control.

TONGA

The name Tonga is composed of *to* (to plant) and *nga* (a place). It also means “south.” Recent archaeological findings suggest people arrived in the archipelago or “land lying in the south” about 1500 BCE from Fiji, located northwest of Tonga. These first colonists, seafaring ancestors of the Polynesians, were a culture distinguished by Lapita pottery. The Tongan creation myth explains how Maui fished the islands from the ocean.

Another myth describes the first *Tu'i Tonga* (king) as son of Tangaloa, a god, and a human female. This sacred line of kings and queens ruled from the 10th century CE to about 1470, when the reigning *Tu'i Tonga* transferred his temporal powers to his brother under the title of *Tu'i Ha'a Takalaua*. A similar transfer of power about 1600 resulted in the creation of a third line of monarchs, the *Tu'i Kanokupotu*.

Many believe Captain James Cook, who called Tonga the “Friendly Islands” when he visited between 1773 and 1777, was the first European to arrive. Actually, Dutch navigators Jakob LeMaire and Abel Janszoon Tasman had been there already, in 1616 and 1645, respectively.

Volcanic undersea mountains form two roughly parallel chains of islands. The western column is higher, having been raised well above sea level by

repeated volcanic activity. Four of these islands still erupt. The lower islands in the eastern chain can resist erosion because of caps made of coral rock and limestone reefs. There are 169 islands, 36 of which are inhabited by 110,000 people. The capital is Nuku'alofa, on Tongatapu Island. The total area is 289 square miles.

A nation of paradoxes, Tonga was one of the most centralized and highly stratified societies in the Pacific before proclaiming itself an independent constitutional monarchy in 1875. Even though change of government by constitutional means has occurred in Tonga, as it has in most Pacific nations, under the present constitution it is not likely that the government would yield its emphasis on status, titles, and hegemony following a general election. All land is owned by the king, nobles, and government and leased to citizens who pay tribute, usually with food; foreigners cannot own land. Although there are parliamentarians elected by commoners today, these are outnumbered and outvoted by representatives of nobles who are unlikely to go along with any changes proposed by the former. For the most part, commoners are still excluded from effective participation in government. The current system is undergoing challenge from an active pro-democracy movement that seeks greater accountability. Aristocrats who do not want to change the current system claim monarchy can respond more quickly to the needs of people than democracy

could. They suppress calls for reform and manage to intimidate critics by means of court actions and withdrawal of publishing licenses.

Tongans are a proud people with familial bonds to the land. Social practices grounded in loyalty to kin as well as respect for elders and the “old ways” of telling stories in song and dance; making medicines from plants; raising root crops, maize, watermelons, tomatoes, tropical fruits, fowl, livestock and timber; fishing reefs; weaving baskets; beating bark cloth; celebrating; and drinking kava together have enabled the small nation to survive challenges ranging from battles between chiefs to the arrival of trade ships in the 17th century and exposure to outside commerce in the 20th. Tongans sell fish, handicrafts, coconuts, pumpkins, and vanilla to others, but they are critical of the values of visitors and of the capitalist, individualistic, mass society from which they come. They want to maintain difference between themselves and the rest of the world; yet they covet the West’s material wealth and comfort. Many have migrated to New Zealand, Australia, and the United States to find work and send remittances back to family.

Another paradoxical fact is that these warm, friendly islanders, predominantly Christian and both generous and hospitable, used to be skilled navigators and fierce warrior cannibals who had political and cultural influence over neighboring islands until two hundred years ago. Then they fought internally; civil war broke out in the 1780s. With a kingship believed to be partly divine in origin and an executive below the king determined by clear principles of inheritance from one generation to the next, there was no need for internal contests to decide who would rule until a succession of brothers held senior titles that made each an eligible heir. Aggression subsided in the 1790s but erupted again at the end of the decade with a political assassination. Sporadic but often bitter warfare continued for twenty more years. The old political system was demolished in this period, then reconstructed in the late 1820s in modified form.

Experts attribute the survival of the new system to the adroit leadership of George Tupou I, a high-ranking chief descended from persons who held the title *Tu’i Kanokupotu* and a convert to Christianity who introduced a Constitution in 1875 that eliminated the absolute power of chiefs. He was considered the only person able and willing to bring Tonga under united rule. He issued a new law code in 1850 and secured international recognition by issuing a second, bolder

code of law in 1862 that included emancipation of people from serfdom, compulsory education of children, regular taxation, and new principles of land distribution.

Although Tongan is the official language, widespread knowledge of English resulted while Tonga was a British protectorate for the first 70 years of the 20th century. Today villagers know little English but enjoy an oral tradition of proverbs, religious epics, genealogies, poetry, fables, and myths. English is taught as a second language in elementary and secondary classrooms and used in business transactions in major towns. Tongan, meanwhile, is spoken in streets, shops, markets, schools, offices, and churches. Tongans are proud of nearly 100% literacy. Three separate Tongan dialects have been used in ceremonies by *ha’a mata-pule* (talking chiefs) whose task it is to mediate encounters between king, nobles, and commoners during tributes to the king on each major island once a year and whose place in the hierarchical social structure is below kings and nobles, and ahead of would-be talking chiefs and commoners.

Kin groups include married couples and their children and extended family living in different households. Everyone contributes to parenting, and adoption is frequent. Traditional brother–sister avoidance is enforced, and 10-year-old boys must sleep in a separate house. Brothers and sisters do not watch videos together nor discuss topics such as sex.

Gender and age establish hierarchy at any level of society. Inherited titles and land may follow a male line of descent, but females have higher status in the social hierarchy. An egalitarian attitude exists at home and in the marketplace. Human rights are generally well respected in Tonga, although political dissent is suppressed. Other nations are watching with concern the threat to freedoms of speech and press in Tonga.

TOOLS AND EVOLUTION

There is an inherent problem within African Acheulian and Middle Stone Age assemblages research: how to recognize culture and ethnicity and the period in which hominins evolved the cognitive ability to invent social solutions to perceived or real ecological and functional challenges. There also exists the challenge of establishing the relationships between the stone tool assemblages and the cultures of which the knappers were a part.

These problems are investigated through functional, compositional, ecological, and temporal analyses of the Acheulian handaxes, the Acheulian-Middle Stone Age transition, the timing of the occupancy of the central African rain forests, the Still Bay level at Blombos Cave, and the Middle Stone Age layers at Klasies River. African archaeologists have used the typological categories introduced by Goodwin and Van Riet Lowe and the lithic Modes of Clark to create a conceptual framework in which they could operate; however, the framework has produced tensions and constraints whose chronological, cognitive, cultural, functional, and environmental problems have become prevalent in the Middle and Late Pleistocene research paradigms of Africa.

The development of more sophisticated models is required on an integrated regional basis in order to capture and subsequently extrapolate the differential expressions of lithic technology, temporally and spatially.

Background

John Goodwin and Clarence van Riet Lowe published a seminal work in 1929 which has influenced African archaeology ever since. Entitled *Stone Age Cultures of South Africa*, Goodwin and Van Riet Lowe proposed that the Stone Age sequence be subdivided into the Early, Middle, and Late Stone Age (hereafter shortened to ESA, MSA, and LSA). By proposing their alternative scheme to the European sequence of Lower, Middle, and Upper Palaeolithic, Goodwin and Van Riet Lowe were emphasizing the distinctiveness of the African archaeological temporal sequences and typological assemblages.

The post-World War II period witnessed the beginnings of a major overhaul of the archaeological

discipline. Beginning with the advent of radiocarbon dating in the 1950s and continuing with the New Archaeology's hypothetico-deductive-nomological model, archaeology drew upon and attempted to reorient itself within the hard sciences. Goodwin and Van Riet Lowe proposed a classificatory scheme that was formally approved by the Third Pan-African Congress held in 1955.

The classificatory schemes outlined above for Africa and Europe were taken a step further and recombined by J. D. Clark on the basis of dominant lithic technologies. His resulting Modes of Technology divide the history of stone tools into five modes. The modes are held to be reflective of raw material availability, functional differentiation and manifestations of hominin technological strategies. The table outlines the current status of lithic mode recognition and classification.

<i>Technological Mode</i>	<i>Industry and Fossiles Directeurs</i>
Mode 1	Oldowan, Early Stone Age (choppers and flakes)
Mode 2	Acheulian, Early Stone Age (bifacial hand-axes)
Mode 3	Middle Paleolithic, Middle Stone Age (prepared cores, points)
Mode 4	Upper Paleolithic (retouched blades)
Mode 5	Mesolithic and Late Stone Age (microlithic composite flakes and blades)

After Clark, 1977, and Foley & Lahr, 1997.

These technological strategies are manifestations of behavioral adaptations whereby knowledge and culture are transmitted through social learning. The accumulated repertoire limits the risks of invention in technological and cultural evolution, but permits their expression in a wide diversity of situations through socially mediated responses to particular internal or external stimuli.

The mode classificatory scheme was built on the assumption of inbuilt progress in the evolution of stone tool technology. In this view, progress, combined with varying systems of inheritance, was enough to explain the contrasting time spans of the different lithic technologies. This framework was the intellectual birth of the model seeking to explain the advent of "modern human behavior" as a revolution occurring between 50 kya and 40 kya. It became clear there were serious inherent defects. One such

Source: © iStockphoto/Philippe Pellerin.

problem and its implications for African stone tool research involved the transitional boundary between the Acheulian and the MSA.

Interwoven with the investigations on the transitional period from the Acheulian to the MSA is the issue of how the stone tools were manufactured, what materials were used, the sources of the raw material procurements and what is signified in terms of the knappers' functional and cognitive capacities.

Inquiries into the uniformity or regional distinction of Acheulian handaxes need to account for the composition of stone procured, the flaking properties of the raw materials and the reduction sequences used. A 1990 study by Thomas Wynn and Forrest Tierson looked at Middle Pleistocene samples gathered from four regions of the world, including East Africa. The East African sites of Olorgesailie, Isimila, Kariandusi, and Lewa were selected. The results obtained in particular from Kariandusi reinforce previous studies that the form of the Acheulian bifacial implements was constrained by the raw materials utilized. Through function analysis, Wynn and Tierson were able to achieve a 75% success rate in sorting the Kariandusi handaxes into their correct raw material constituents. The remaining unaccounted for 25% was attributed to conscious cultural expression. However, given the time span of the East African sites chosen for the study (700–200 kya), Wynn and Tierson failed to adequately account for the possibility of temporal variation as viable alternative explanation.

This is an argument that has been picked up by Iain Davidson, in particular. Davidson rejects the hypothesis that the Acheulian handaxes were a product of

deliberate intentionality. He argues that the observed patterning is insufficient evidence of the intent of the knappers and demonstrates the cognitive inability to communicate using symbols. Defined as “the assumption that the objects which the archaeologist recovers represent final forms corresponding to the self-consciously articulated, prior intentions of their one-time makers,” the Davidson's Finished Artifact Fallacy hypothesizes differences between artifacts which are distinctive, repetitive and standardized, and those artifacts which have had form imposed upon them.

In place of the Finished Artifact Fallacy, Davidson advocates the re-examination of the Acheulian industry due to archaeologists having conducted selective studies through choosing which materials to analyze. He argues that archaeologists have unwittingly introduced patterns based upon both their selections and the procedural practices and technological steps used by the makers of the artifacts. This makes it extremely difficult to arrive at an understanding of the intentions and cognitive capabilities of the makers without eliminating and understanding these biases and steps. Davidson argues that the Acheulian handaxes are examples of this, as it is impossible to distinguish between flakes originating from cores or handaxes, and that this is therefore an indicator to the lack of guiding principles on the part of the knappers.

The functional hypothesis that the type of raw material chosen determined the shape and size of the Acheulian handaxe remains a persuasive argument. Reinforcing this hypothesis is the experimental archaeology showing resharpening reduction is capable, through three to four episodes, of altering an Acheulian handaxe into a Developed Oldowan handaxe. However, this demonstration of a plausible two-stage life suffers from the same inherent flaw as the Wynn and Tierson study: conflation of temporal variation.

Only two of the several clusters of late Acheulian sites mapped by Garth Sampson at Seacow Valley, South Africa, ranged within 1 kilometer of their corresponding quarry. The vast majority of the sites were situated near river beds and still within easy access distance to the quarries. The artifacts show three

developments over the symmetrical bifaces of the early Acheulian. The developments have been categorized as congruency, three-dimensional symmetries and broken symmetry. An example of the latter is the twisted profile handaxes that first appear ca. 350 kya. Wynn poses the question as to why symmetry would have been imposed and queries whether it might be connected with mate selection, a hypothesis also advocated by Kohn and Mithen but which ultimately rests on an untestable psychological basis.

Lithic assemblages have often been held up as representative of cultural entities, through either *in situ* cultural differentiation or population movements into new raw material niches permitting expansion of existing or development of new repertoires. Illustrative of this is the distribution pattern across the landscape of the Lupemban industry, dated to ca. 270 kya, particularly in relation to the prior Acheulian and Sangoan site patterns.

Increasing evidence has been put forward by Lawrence Barham for the Lupemban industry exhibiting a cognitive, technological, and adaptive sophistication not witnessed previously. Using environmental reconstructions, it is claimed that while the Sangoan exhibits a resemblance in distributional patterns to the Acheulian, there was an important difference which contributed to the emerging pattern that was to become the Lupemban industry: the Sangoan sites are generally found in habitats of higher productivity. This hypothesis holds that the loosening of ties to waterways and lakes permitted the subsequent knappers of the Lupemban industry to expand into and inhabit the Congo basin which, in the paleoenvironmental reconstruction, was forested.

Barham builds on the work done at Kalambo Falls, and his own work at Mumbwa Caves and Twin Rivers, to plot the known distribution of Lupemban sites over maps of the paleoenvironmental reconstruction of central Africa. The resultant model takes into account the glacial/interglacial cycles of African biogeography as well as lithic assemblage distribution mappings of 36 years ago. The problems within the model are manifest and raise serious concerns over both its accuracy and the conclusions drawn from it, namely that the central African rain forest was occupied at the time of the Lupemban.

Although climatic fluctuations can be deduced from the Congo fan deposits, these deposits do not extend beyond 200 kya. Neither do there exist reconstructions of climatic sequences from the internal

Congo basin itself. While it is claimed that Lupemban sites existed in closed forests in Equatorial Guinea, through marine pollen profiles, more precise analyses are required for local areas and from the sites in question.

Barham claims that the Lupemban industry reflects a new composite stone tool technology: backed blades and segments, bifacial lanceolates, notched bifacial points and tranchets. These, according to his hypothesis, are the tools of a specialized hunting and gathering culture with the technological and social capabilities of extracting the nutritional requirements from closed canopy plant and animal resources.

Although Barham recognises the economic arguments brought to bear against an early occupation of the rain forests of central Africa, he fails to adequately address the concerns. The nutritional values of plant and animal resources in closed canopy forests are such that it appears unlikely modern hunter-gatherers occupied closed canopy forested areas for substantial periods of time prior to the latter portion of the LSA. If this turns out to be correct, then serious questions have to be posed about the viability of hominins occupying and surviving in these environments 270 kya.

Alternative hypotheses are required to be formulated which do not relate the Lupemban composite assemblage to a new cultural, and possibly ethnic, grouping adapted to survival in forested and semi-forested environments. More profitable lines of inquiry may look at how the Lupemban was adapted to savannah and semi-woodland areas, the variability in intersite assemblages and how the composition of this expression could be compared culturally and technologically with contemporary and later variable compositions.

Still Bay sites are only found in sub-Saharan Africa and are predominantly along the East Cape south coast. The dating of the Still Bay industry has long been an unanswered question in southern African archaeology. The results of radiocarbon dating on charcoal and shell from the Still Bay levels at Blombos Cave, on the southern Cape coast of South Africa, should be considered as infinite dates. Recent luminescence dates suggest an age of ca. 100 kya for the earliest MSA layer, BBC 3. The Still Bay points come from the BBC 1 phase which underlies a sand dune layer dated by optically stimulated luminescence to ca. 70 kya.

The diagnostic feature of the Still Bay industry is the leaf-shaped, bifacially retouched point possibly

used as a spearhead. The primary raw material used was silcrete. Length can vary from two to three centimeters to the very large “Blombos point.” Deacon has suggested that this assemblage is indicative of craft specialization, because its function as a hunting spear point could possibly have been better served had the points been smaller. This hypothesis therefore accords stylistic symbolism to the artifacts.

Although there are no Mode 3 occurrences in Africa, and thus no African antecedent for the European Upper Paleolithic, certain viewpoints grew up around the question of the perceived lack of variation and change in the MSA. These are problematic from the viewpoint of the temporality and compositional significance of the Howiesons Poort industry in southern Africa. No site has been more central to the development of the debate than Klasies River.

Klasies River is situated on the southern-east coast of South Africa. The site is comprised of five MSA and one Holocene deposits from caves 1, 1A, 1B, 1C, and 2.

Oxygen isotopic analyses and uranium disequilibrium dating place the basal layer in correlation with MIS (Marine Isotope Stage) 5e. It has been proposed that the SAS member (MSA I and II) is in the region of 90 kya and the Upper Member (MSA III and IV) no less than 50 kya, thus out of the range of radiocarbon techniques. Contra Parkington, who hypothesized that southern African Howiesons Poort assemblages may also postdate 50 kya, the Howiesons Poort layer is underlain and overlaid by MSA II and III respectively. The Howiesons Poort is generally correlated with MIS 5a and 4, the boundary of which is estimated at around 74 kya.

Retouched blades were Clark's *fossile directeur* for Mode 3. Yet although blades are one of the main characteristics of the MSA and backed artifacts of the Howiesons Poort, neither should be viewed as anticipating the advent of a lithic assemblage on a separate continent. In the case of the Howiesons Poort, there is up to 25 kya in time between it and the Aurignacian.

The correlation of the Klasies River MSA sequences with periods of changing environmental conditions and the changing assemblage compositions led Ambrose and Lorenz to propose an ecological deterministic model of changing social conditions. Through analyses of resource structure, they claimed that the MSA inhabitants failed to respond to the changing environmental conditions in the same flexible patterns as their Holocene counterparts. These results indicated that their socioterritorial and technological

systems were determined solely by the resource ranges available for exploitation with the least energy output.

While recognizing that the environmental stress caused by ecological changes at the start of the Howiesons Poort led to the increased resource ranges postulated by Ambrose and Lorenz, their hypothesis fails to explain why access to new raw materials would automatically result in the advent of new stone tool artifacts. In order for their functionalist ecological hypothesis to account for these new artifacts, Ambrose and Lorenz would be required to “ascertain for every concrete case the causal chain which linked the initial natural impetus and the resultant cultural transformation.”

Hilary Deacon has proposed a structuralist alternative whereby the environmental stresses placed on the Howiesons Poort occupants resulted in attempts to maintain previously existing social structures and population levels: Instead of adapting to nature, they modified their behavior. Remnants of their adaptation can be found through examination of their stone artifacts in functional terms. He concludes, through analogies with backed artifacts from the southern African Wilton assemblages (8–4 kya), that the backed segments and trapezes are best regarded as hafted projectile points used in hunting; this analogy has subsequently been weakened by microwear and experimental analyses suggestive of the Wilton segments being components of knives instead of functioning as arrowheads. The MSA backed pieces are larger and were more likely to have been spear points and barbs. Ethnographic writings on the Bushmen record that projectile points carry both stylistic and social meaning, marking social and linguist groups, and are used as exchange gifts. The appearance of backed artifacts in the Howiesons Poort is, therefore, viewed as an attempt by the toolmakers to mark out social boundaries and the intensification of social networks under a period of environmental duress. As the climatic conditions improved toward the onset of the MSA III, the factors that influenced this cultural selection for a high level of symbolic behavior therefore gradually fell away.

The challenge posed by Deacon's generalized hypothesis was taken up by Sarah Wurz who, in 1995, took a random surface sample of Howiesons Poort artifacts from Cave 2. Comparisons were made with the 1968 Cave 1A top cutting (119 336 artifacts) sample (KR1A-68) of Singer and Wymer by using the use of the same major typological categories: waste, used pieces or edge-damaged pieces, and formal artifacts.

Lindly and Clark theorize that the continuous lithic industries reveal no evidence of stylistic patterning over time; they concede that the Howiesons Poort layers (Layers 10–21 of Shelter 1A) demonstrate a shift in the MSA to retouched stone tools. However, they make no reference to a recent technological and typological analysis of the MSA II stage at Klasies River Mouth, conducted by Thackeray and Kelly, that concludes the finished product does not necessarily represent the way things are in practice, but rather the way things should be ideally.

Howiesons Poort blades occur in greater frequency than their typical MSA predecessors and descendants, 17.44% versus 0.98%. There is also a lack of retouched and used artifacts. The backed artifacts have previously been suggested by Thackeray to be less standardized than their Later Stone Age counterparts, a conclusion countered by Wurz. The variation coefficient obtained falls within that recorded for the LSA, demonstrating the backed artifacts from the Howiesons Poort and the Later Stone Age were designed with a comparable mental construct of their shape parameters. Backed artifacts from the MSA Howiesons Poort and the Later Stone Age Wilton are design types of the same kind, although the Howiesons Poort backed artifacts range from two to three times their size.

Strengthening Deacon's argument, Wurz draws parallel between demonstrable archaeological and ethnographic usage of backed artifacts as projectiles. Amongst the Bushmen these projectiles are imbued with symbolism. Projectiles can take many possible forms and therefore the form chosen during the Howiesons Poort was a material action of choice governed by social rules and by extension was a form of modern behavior.

By comparing the raw material samples of KR2–1995 and KR1A-68 in terms of quartzite and nonlocal rock occurrences, Wurz determined that a marked difference is evident in the raw material composition. Around 27% of its Howiesons Poort artifacts were manufactured from non-quartzite (and consequently nonlocal) raw materials. By contrast the unbiased KR2–95 is comprised of 4% non-quartzite artifacts, with a high percentage (39%) of the retouched artifacts made from these materials. A high degree of selection is therefore present in the choice of raw materials.

Wurz used the analytical *chaîne opératoire* approach in analyzing the choice of raw materials by the Klasies River people for their stone tools. Nonquartzite

materials increase in numbers only in the middle stages of the Howiesons Poort, before again falling to low levels. Wurz attributes these raw material changes to conscious choices.

Wurz analyzed the backed artifacts in terms of segments (crescents), intermediates and trapezes to determine whether a relationship could be established between the form and extent of backing, and the resulting artifact. The waste materials are also regarded as by-products from the main design of shaping cores for the removal of blanks. Consequently, the production and subsequent use of backed artifacts were likely to have been the result of decision making and deliberate steps taken.

The sites of Kapthurin and Herto exemplify warnings about using typology uncritically as chronology. The mixture of the typologies in the lithic assemblages over a period of time in excess of 100 kya is a timely reminder that a direct correlation between typology and a set chronological timeframe is an uneasy assertion. The mixing of the Herto assemblage is on a greater scale than has previously been envisaged. Kapthurin poses a particular problem to mode model formulations, as the assumptions of progress inherent within do not take into account the mix of technological strategies that were employed.

It is therefore questionable whether the onset of Mode 2 is indicative of hominins having developed the ability to impose symmetry upon a stone tool or whether it was an extension of the process of tool reduction developing out of the Oldowan, Mode 1. It would be unwise to postulate a single purpose and function for Acheulian bifaces that flourished and evolved over 1.5 million years, and single purpose ideas such as sexual selection are untestable. It is more likely that the current opposing models of symmetry and reduction sequences are disguising real temporal and productive variations, which require greater chronological and stratigraphic control over the source sites to elucidate. The sequences involved are complex and varied and what is visible is the by-product of that variability, variability that itself might have changed over the course of hundreds of thousands of years. This changing variability is most vivid in the late Acheulian within the transitional period to the MSA, with Acheulian handaxes being knapped by the Levallois method.

The variability of the new MSA assemblages has led to hypotheses over cultural markings and new population settlement patterns. A recent hypothesis

by Barham regarding the occupation of closed canopy forests in Central Africa is questionable on the grounds of nutritional deficiencies of rain forest resources and on the low level of climatic resolution available. Questionable too is Lahr and Foley's linkage of the appearance of the new technology with the advent of a new *Homo* species, *Homo helmei*, thus linking anatomy with technology and culture.

The Klasies River MSA I and II assemblages date to the last interglacial but, contra the expectations of the Ambrose and Lorenz, there are important differences in their composition. MSA I follows a blade production strategy, with the MSA II a Levallois-like point manufacture. These lead into the Howiesons Poort via a tendency toward smaller blades in the upper MSA II sequence. This cuts across Ambrose and Lorenz's simplistic technological-ecological indicator models, undermines Parkinson's use of the Howiesons Poort as a transitional phase to the LSA, negates Singer and Wymer's use of the Howiesons Poort for the arrival of new ethnic inhabitants and is a powerful indicator of changing cultural traditions which are reflected in the compositional makeup of the assemblages.

Ambrose and Lorenz see the Howiesons Poort occurrence as an adaptive response to environmental pressures that resulted in mobility pattern changes and the procurement of higher-quality raw materials for their stone tools. This viewpoint therefore presupposes that the technological changes are not related to stylistic preferences and expressions. To say that the environment determined their responses ignores the mental processes behind the conscious choices involved in making the changes they did. The Klasies inhabitants, for example, had perfectly good quartzite raw material available on the beaches, yet during the Howiesons Poort they imported silcrete from 20 kilometers away to manufacture the backed tools. The manufacture of the Howiesons Poort artifacts was, therefore, more likely to have been governed by social rules.

Deacon has proposed that the Still Bay is an example of a MSA craft specialization industry. Blombos and Klasies River are not a large distance apart, which suggests that the Klasies River inhabitants did indeed have access to such knowledge but made a cultural choice not to use it. Deacon suggests that craft specialization resulted in reciprocal trading, but it still remains to be determined first whether the Still Bay industry is indeed a form of craft specialization. What is clear is that the Still Bay industry points

do not make for better spear points than other smaller bifacial tools, and this may have had something to do with a symbolic value being attached to them.

From before, but especially after, the publication of *Stone Age Cultures in South Africa*, African archaeologists have been increasingly concerned with typology. Cemented in Clark's lithic Modes, these typologies fostered a belief in a progressive lineage of lithic assemblages in Africa and contributed in particular to the Howiesons Poort being viewed as a transitional phenomenon to the LSA.

The Acheulian handaxes have been used as settlement markers in relation to their quarries and indicative of riverine resources at Seacow Valley. Kapthurin and Herto have mixed Acheulian and MSA industries, and together span of ca. 150,000 years which also covers the period in which the Lupemban is probably inaccurately claimed to have penetrated the central African forests. The changing nature of the manufacturing process of the Acheulian handaxes, the composition of the Lupemban industry and the changing compositional nature of the MSA industries at Klasies River are suggestive of evolving cognitive abilities that are most prominently expressed in the Howiesons Poort. Although environmental factors would have influenced the territorial ranges of the MSA peoples, conscious choices were made as to raw materials for their stone tools.

The untidy transition from the Acheulian to the MSA, the appearance of the regional Still Bay industry at Blombos and the integrity of the MSA at Klasies River, are strong arguments against simplistic lithic mode and cognitive-environmental proposals. The innovation in the Still Bay and the Howiesons Poort, while maintaining lithic patterned links to the preceding and later MSA assemblages, demonstrates the folly of linking new lithic expressions to incoming migrants possessing a different culture; this is paralleled in the caution over linking the Lupemban to new cultural adaptations by a new *Homo* species on the basis of weak data.

Sophisticated regional models are required, taking into account the full range of technological, faunal, geological, and taphonomic processes. These new models must incorporate variable cultural expressions, constrained adaptations to changing environmental conditions in terms of the existing cultural and social repertoire of the inhabitants, and the desire to link form to function when such linkages should

be inferred from the data rather than attributed to it and thus constrain it technologically and temporally.

with a family ancestor and bestowed upon his lineage the right to tell its story and depict its image. Crests were cherished family privileges that embodied family history and contributed to its status. When a family raised a pole that depicted one or several of its crests, it had to sponsor a potlatch to validate this display and pay the witnesses of its presentation of privileges with quantities of goods.

During their early voyages to the Northwest Coast at the end of the 18th century, explorers and traders saw almost no poles. Seaman John Meares sighted one in 1789, and in 1791 John Bartlett drew the earliest known depiction of a totem pole, a 40-foot-high frontal pole in the Haida village of Dadens on Haida Gwaii. Before that time, no traveler had described or illustrated exterior poles. It would only be during the 19th century that villages from the Tlingit to the Kwakwaka'wakw erected large numbers of totem poles.

The totem pole presumably developed from several aboriginal types of monumental art: interior house posts, facade paintings, and mortuary carvings erected out-of-doors. It is likely that the exterior columnar totem pole originated in precontact time among the Haida or Tsimshian. Totem poles were the single most striking type of 19th-century Haida art and increased in numbers from few in early contact times to abundant by the 1860s. While only two stood in Dadens in the late 18th century, by the first decades of the 19th century, large numbers of poles stood in both Haida Gwaii and in the Kaigani region.

Probably the increased wealth and growing competitiveness between chiefs inspired the flourishing of totem poles. Chiefs with greater riches wanted more impressive visual expressions of their high positions, and consequently commissioned taller and more numerous poles. Artists using metal tools they obtained in trade carved larger and more complex works of art. Commercial paints facilitated their decoration. After the northern British Columbia tribes invented the pole, it spread first to the Kaigani region of Alaska, north to the Tlingit, and in the later 19th century, south to the Wakashan groups. By the 1880s, the Haida had virtually ceased carving poles, but it was at around that time that the Kwakwaka'wakw began to erect more and more of them. It is possible that these express an ostentatious disregard for the British Columbia potlatch law, for poles were meaningless *without* the potlatch that validated their erection.

TOTEM POLES

The tall, elaborately carved and painted totem pole represents the most famous and well-known type of Northwest Coast art. Images on these carvings depict crests, beings that in some time in the past interacted

Poles became widely known outside the Northwest Coast as a result of the combined effects of tourism, world's fairs, and museum collecting. In the 1880s, steamships brought sightseers up the Inside Passage. Fascinated by the totem poles they saw, tourists placed these monuments among the "must sees" on every itinerary. Poles themselves began traveling to distant places when they were presented at several world's fairs; in the 1876 Philadelphia Centennial Exposition, the Smithsonian Institution presented publically its first totem poles. For the 1894 Chicago World's Columbian Exposition, Franz Boas assembled an impressive array of poles, which eventually became part of the Field Museum's collection. And, at the 1904 St. Louis Louisiana Purchase celebration, an impressive array of Alaska totem poles stood before the Alaska building. These ended up returning to Sitka, where copies stand in the National Historic Park there. Other museums collected poles, and by

the 1920s, few remained in their originating communities, for many had left for points south and east.

In the first several decades of the 20th century, both the Canadian and United States governments recognized the value of totem poles as tourist attractions and supported projects for the restoration of the remaining totem poles that, often decayed and deteriorating, still stood *in situ*. Instead of disinterestedly allowing these monuments to be taken away and erected in distant museums, efforts began to preserve, restore, and when necessary, copy the originals, now viewed as treasures. Between 1926 and 1930, the Canadian government collaborated with the Canadian National Railway to restore 30 Tsimshian poles along the railroad's Skeena River route. The Depression-era "Indian New Deal" restoration program propelled Alaskan totem poles into public attention. In 1938, the Indian Civilian Conservation Corps (CCC), under the supervision of the U.S. Forest Service, began restoring totem poles, most

of which today stand in Ketchikan, the first stop on the ferry from Washington state. Others are in Wrangell and Sitka.

After World War II, the two major British Columbia museums, the Royal British Columbia Museum in Victoria (originally called the British Columbia Provincial Museum) and the Museum of Anthropology on the University of British Columbia campus in Vancouver, initiated salvage and restoration projects that have become models of cultural preservation. In 1949, the University of British Columbia purchased several Kwakwaka'wakw poles, house posts, and an eleven-piece house frame, which they planned to erect outdoors on the campus. From 1949–1951, Kwakwaka'wakw master carver Mungo Martin was in residence at MOA, restoring his and carving new poles. In the early 1950s, the Royal British Columbia Museum in Victoria hired Mungo Martin to restore or replicate some of its poles. Over

Tony Hunt totem pole, Stanley Park, Vancouver, British Columbia, Canada

the years, Martin worked with his son David, his adopted daughter's husband Henry Hunt, Hunt's son Tony Hunt, and Bill Reid, a man of Haida ancestry who was to become one of the most highly regarded northern Northwest Coast artists.

After the 1960s, with the reinvigoration of artistic creativity in the region, totem pole carving began to proliferate once more. New poles were raised in a variety of contexts including museums, universities, and Native communities. Among the most well-known living Northwest Coast totem pole carvers are Nathan Jackson (Tlingit), Robert Davidson (Haida), Calvin and Richard Hunt (Kwakwaka'wakw), David Boxley (Tsimshian), and Tim Paul (Nuu-chah-nulth). These and other artists are training younger carvers who will continue the tradition of Northwest Coast totem pole carving.

TOTEMISM

Totemism is often described as a kinship system linking humans ancestrally to powerful symbols present in the natural world. Totemic systems are said to be built around totems, which are fundamental signs of “kinship” running between human societies or individuals and the surrounding world. The term “totem” comes from “*ototeman*” in Algonquian (the largest family of languages native to North America) and the tribe of the Ojibwa who were found in the Great Lakes region of the eastern North American woodlands. Its original meaning was “his brother-sister kin.” The grammatical root, *ote*, identifies an exogamous relationship between brothers and sisters born to the same mother. The classical definition was made by James Frazer that totemism “is an intimate relation which is supposed to exist between a group of kindred people on the one side and a species of natural or artificial objects on the other side, which objects are called the totems of the human group.”

Totems connect human societies to the surrounding world and allow humans to construct social hierarchies that mirror those observed in nature. Totems are most frequently animals though they may also (rarely) be a plant, or even inanimate objects or forces such as the sun, moon, rain, or thunder. Generally totemic societies also have sacred animals and plants, which are not totems. They generally have essentialist beliefs in the animistic qualities of things observed in nature and are most frequently shamanistic. Animals, plants, and even natural phenomena are viewed as having the qualities of living things, including the possession of souls. Animacy may be attributed to spirits dwelling in objects, or the object or phenomena may itself be viewed as a life force. Many anthropologists see totemism as a mechanism for constructing order

in society and the surrounding world from the chaos of the universe.

In operation, a totem is generally considered taboo to the members of a clan who identify with that totem. As a rule of thumb, they cannot kill it nor consume its flesh (outside of occasional totemic rituals). The totem is seen as a powerful social feature that binds together the members of a totem clan. All clan members who share a totem are regarded as related kin. In this regard, totemic clans are also generally considered exogamous.

The term made its way into social theory in the late 19th century with the publication of John F. McLennan's comparative study "The Worship of Animals and Plants." As was in vogue at the time, he proposed an evolutionary stage in human development characterized by the worship of plants and animals. This was challenged by E. B. Tylor, who saw totemism as a means for people to classify the world and nature but did not see it as a basis for organizing religion. Instead, he saw totemism as linking specific clans to specific animals, rightfully pointing out its kinship role uniting clans and animals in both kinship and mutual alliance. In 1910, Sir James George Frazer published his monumental four-volume work *Totemism and Exogamy*, in which he compiled all known accounts of the subject to date. Frazer's own work had been conducted in Australia and Melanesia, where he observed the role of totems in beliefs related to conception and childbirth. He proposed that in primitive religions, conception was thought to occur when a spirit of a plant or animal impregnates a woman. In that way, the child has a direct relationship with the totem. He suggested that totemic beliefs are related to explaining reproductive processes. The sociologist Émile Durkheim, who was interested in early forms of religion, examined totemism in 1912 as part of his efforts to identify the ancient and "pure" forms of religion. He proposed that totemism may have been one of these elementary forms of belief. He saw the concept of the totem as a symbol of group consciousness that allowed primitive societies to conceive of the idea of sanctity.

In a movement away from the idea that totemism reflected a primitive or elementary form of religion, Franz Boas rejected any historical unity in totemic societies and proposed that such generalization existed only in the minds of ethnologists. He observed, in classic particularist form, that there existed no common psychological or historical origin for the practice and that since totemic practices exist in such a wide range

of individuals associated with all possible types of social organizations and cultural contexts, the phenomena defies any definition that lumps it into a single category. A. R. Radcliffe-Brown was also unconvinced that institutions of totemism were real. He viewed the study of totemism as being compilations of beliefs and elements taken from different areas and institutions having in common only that they represent an intersection of the social and the natural. Another contemporary, Bronislaw Malinowski, maintained that totemism was an institution that could be studied comparatively, including from both biological and psychological frames. He considered totemism not so much as cultural phenomenon but as a desire to satisfy basic human needs in the context of the natural world.

Throughout the mid-20th century, the role of totemism in religion and social organization continued to be debated. Elkin, discussing totemic society in southern Australia, saw the belief as a means for humans to find solidarity with nature, thereby acknowledging links between humans and the world they live in. By classifying and giving order to the world through totems, aborigines were able to respect and worship the entire natural world. Elkin's idea that totemism was an organizing principle for religion was heavily criticized by Claude Lévi-Strauss, who saw in totemic societies various types of related religious phenomena extending well beyond totems.

Lévi-Strauss was most certainly influenced by Radcliffe-Brown, and he endeavored to expand on his writings. From a structural perspective, he viewed totemism as reflecting the abstract polarities of nature and culture present in human cultures. These oppositions, or polarities, could be charted to illustrate the complex relationship that, on the one hand, recognized natural realities such as animals and plants, and on the other, various groups and individuals who identified themselves as related to specific types of animals or plants. He discussed four specific types of totemic oppositions, or relationships, that could exist between nature and culture: (1) a group identifying with a specific species of animal or plant, (2) an individual identifying with a species of animal or plant, (3) a specific animal or plant identified with an specific individual, and (4) a specific animal or plant identified with a particular group.

TOYNBEE, ARNOLD JOSEPH
 (1889–1975)

Considered one of the most influential historians of the 20th century, Arnold J. Toynbee and his interpretations of the world's civilizations have become standard reading for generations of students and scholars alike. Like Oswald Spengler before him, Toynbee wrote about human history as a series of civilizations, separated not by national characteristics, but by culture and religion. His major work, *A Study of History*, is a ten-volume piece written between 1934–1961.

Born in London, England in 1889, he attended both Winchester College and Balliol College at Oxford. After graduation in 1911, Toynbee began his teaching career at Balliol. He went on to teach at the University of London, the London School of Economics, and the Royal Institute of International Affairs. During World War I, Toynbee worked for the British Foreign Office in the Intelligence department and attended the Paris Peace Conference at Versailles in 1919. He served his nation in World War II by working again with the Foreign Office and returned to the Continent as a delegate in the peace talks at the end of the war.

Certainly one of the century's most prolific authors, Toynbee and his many works stand apart in the field of universal history. The scope of his *A Study of History* (sometimes called *The History of the World*) is the entire written history of humankind up to his present time. In it, his premise is that a distinct pattern can be found throughout all human historical experience. He is consistent throughout the ten volumes in describing civilizations that find conflict with other men, physical (nature) forces, or God. These peoples find either success or frustration in working toward a response to these events. Toynbee calls this phenomenon "Challenge and Response." In the last

few volumes of the *Study*, Toynbee seems to find religion to be this "other force" in an increasing number of cases. Unlike Spengler's descriptions of a finite, predictable "life cycle" for each civilization, Toynbee is optimistic. Many civilizations do adapt to overcome whatever forces are arrayed against them.

It is interesting to note that Toynbee asks the question, "Does history repeat itself?" in his book *Civilization on Trial*, written in 1948. Of course, at the time the world's political order was still in flux. World War II had recently ended and the United Nations had just come into existence. The obvious implication of the question dealt with the great military conflicts the West had seen in the previous one hundred years. Would the nations of the world square off again in the next generation as they had done so many times in the recent past? Toynbee asks us to calmly consider that although in many ways history does indeed repeat itself, this does not mean that free will is compromised. Put another way, human destiny is not predetermined, for Toynbee writes that as long as there is life, there is hope, and that humans are truly the masters of their destiny.

In his writings, he saw the purpose of all preceding societies. Throughout history, Toynbee wrote, humanity continued (and still does so) to attempt to rise toward some higher kind of spiritual life. Toynbee believed that that goal has never been reached by an individual society, but perhaps has been reached by individual persons such as saints. He was a tough critic of society, and in his view, humankind is an unfinished project, a work in progress. All the civilizations that we know of have already broken down and gone to pieces, with the single possible exception of our own Western civilization.

Toynbee's politics appear to lean toward a liberal, nearly Socialist view of government. In his book *Change and Habit—The Challenge of Our Time*, he makes the case for an eventual world government. He calls the system of individual countries "a habit," and he maintains that humans can change their habits if the only alternative is disaster. To him, the framework of nation-states and competing military alliances (and the potential for nuclear conflict) between those nations imperils humanity's very existence. Toynbee details the steps required to attain the goal of a world government, including the ways our currently sovereign peoples would have to be convinced that it is in their interest to forgo local representation for the betterment of the human race. The other main benefit

gained from the world government model, according to Toynbee, is a more efficient plan for growing and distributing food to all of Earth's people.

He does recognize, however, the difficulties in getting people to simply get along with one another. Toynbee is correct to say that political equality among diverse peoples is nearly impossible when those involved are also socially, culturally, and physically many miles apart. Social issues such as the equality of the sexes, unique religious practices, and cultural mores vary widely from one region to the next. He makes the argument that within the United States there are still racial issues, particularly in the Old South, that are only one example of how difficult a task it would be to truly unite the world's population under a single ruling government. At the same time, he sees hope, citing the example of both Islamic people and the people of Latin America, who seem to be free from racial tensions among their different populations. Toynbee truly sees only one race—the human race—and feels strongly that artificial barriers such as nationalism must be removed in order for all of humankind to survive. It would appear that at this time in our own history, the nations of Europe, in the expansion of the European Union, are beginning to heed his warnings.

Fellow historians have sometimes criticized Toynbee's methods. One concern focuses on his reliance upon insight and imagination rather than arguments or induction. While some scholars defend his style as an example of using metaphor or simply being poetic, others declare that Toynbee fails to go the extra mile in getting his facts straight, thereby weakening some of his arguments. However, in the end, Toynbee must be given credit for his attempt to document our world's history as a unified one. He has succeeded in showing us that it is at least possible to envision such a future for humankind.

TRANSNATIONALISM

Transnationalism is the idea that flows of transstate migrants and their symbolic and material accoutrements are bi- or multidirectional and ongoing. That is, where previous generations of migrants tended toward making a “clean break” with their societies of origin, many contemporary migrants continue to have ongoing ties with the communities from which they migrated. Transnationalism has been defined in anthropology as “the process by which immigrants forge and sustain simultaneous multi-stranded social relations that link together their societies of origin and settlement. . . . many immigrants today build social fields that cross geographic, cultural, and political borders.” In many sending societies, out-migrants are expected to play an ongoing role. Receiving societies take a variety of approaches, ranging from barring the assimilation or naturalization of migrants to encouraging ongoing dualities of identity or citizenship, but in states representing the full range of these, the number of people living transnationally is on the increase.

Most theorists regard transnationalism as reliant on a new characterization of space. For Arjun Appadurai, deterritorialization is a feature of the new globalized world in which identity is increasingly disconnected, or at least disconnectable, from place. However, Michael Kearney locates transnationalism in its specificity of place, arguing that it differs from global processes that are “decentered” and take place in “global space”; rather, transnational processes are “anchored in and transcend one or more nation-states.” This is reiterated by Aihwa Ong, who regards transnationalism as referring to “cultural specificities of global processes.”

Transnational life is made possible by new technologies that facilitate transportation, communication, and the rapid transfer of funds around the world. Air travel, while too expensive for many migrants to use on more than an occasional basis, nevertheless now whisks people between continents in hours instead of weeks. Migrant remittances sustain or improve the lot of impoverished families. Internet-based forms of communication such as listservs, chat, e-mail, and Web sites facilitate the building and maintenance of deterritorialized communities. These technologies have rendered much of the world “self-consciously one single field of persistent interaction and exchange.”

Transnationalism has given rise to, and is now facilitated by, new institutions. Michael Peter Smith and Luis Eduardo Guarnizo highlight cross-national institutional networks such as sending country governments' outreach to their nationals within host countries. Haiti, which does not recognize dual citizenship but has a Ministry of Haitians Living Abroad, is one such example.

As Sarah J. Mahler notes, many authors at least implicitly distinguish between transnationalism "from below" and "from above." The former concerns the daily lives of ordinary people, and the latter the macro-level political and economic forces dominated by elites. Anthropologists have focused disproportionately on transnationalism from below.

In an article in which he traces the course of anthropology and his own career in it over the past fifty years, Clifford Geertz notes that an interest in transnationalism began in anthropology only in the 1990s, before which it was "not thought to be a part of anthropology's purview" but that now studies of it seem to be "appearing on all sides."

From a Western perspective, travel begins with Europe's fascination with the "Other." Examples of this include religious pilgrimages and the Renaissance expeditions of trade and exploration. Undoubtedly, travel is also tied to colonization by European forces, beginning with the travels of the Portuguese to Africa in 1455 to obtain slave labor when Pope Nicolas V granted the Portuguese the right to do so; followed by the voyages of the Portuguese navigator Bartholomew Dias in 1488 around the Cape of Good Hope; Christopher Columbus's voyages to the Americas

from 1492 to 1502; and culminating with the numerous voyages of exploration of the Pacific by Spanish, French, Dutch and English navigators, mainly in the 16th and 17th centuries. Religious missionaries also contributed to the waves of travelers around the world, oftentimes writing long and detailed accounts of their experiences. Many of these accounts, if read with a critical eye, provide valuable insights into the lifeways of indigenous peoples before the massive changes wrought by centuries of contact. Scholars have found a series of parallels between the accounts written by missionaries during their religious expeditions and 19th-century travel writing.

Travel expeditions were of particular significance to European naturalists in the 18th (such as Sir Hans Sloane (1660–1753) who worked in Jamaica, and Maria Sibylla Merian (1647–1717) who worked in Suriname) and 19th centuries, particularly Charles Lyell (1797–1875), Thomas Henry Huxley (1825–1895), Ernst Haeckel (1834–1919), and especially Charles Robert Darwin (1809–1882). These travels made naturalists aware of the presence and relevance of the fossil record, the distribution of plants and animals, and the presence of societies with different cultures, languages, beliefs, rituals, and customs. Many of these findings contributed to the emergence of anthropology as a discipline. For instance, Sir Charles Lyell, close friend of Darwin and supporter of Darwin's theory of evolution, traveled around the world observing geological phenomena. From findings during these travels emerged the concept of uniformitarianism to explain geological changes throughout history. Thomas Huxley, a self-educated intellectual and author of *Evidence as to Man's Place in Nature* (1863), traveled aboard HMS *Rattlesnake* to Australia as an assistant surgeon from 1847 to 1851. His findings in natural history (particularly zoology) resulting from this trip were published in a work entitled *Oceanic Hydrozoa*. Ernst Haeckel, whose "law of recapitulation" was unfortunately appropriated by the Nazi party to justify nationalism and racism, traveled to the Mediterranean to conduct research on invertebrate groups.

Charles Darwin traveled for five years (1831–1835) as a naturalist aboard HMS *Beagle* on a British science expedition around the world. One of Darwin's best-known stops during this voyage was the Galapagos Islands, which Darwin conceived as "a group of satellites attached to America," with organisms that were physically comparable, organically dissimilar, yet at

Source: © iStockphoto/Christoph Ermel.

the same time closely related to each other. He also traveled to other parts of South America and the world, collecting specimens of plants and animals for further study. This voyage was instrumental in Darwin's development of his famous concepts of co-adaptation and modification of organic beings, and more importantly, his theory of organic evolution by natural selection. This theory holds that variation within species occurs randomly, and that the survival or extinction of organisms is determined by each organism's ability to adapt to its environment. Darwin published these theories in his book *On the Origin of Species by Means of Natural Selection, or the Preservation of Favoured Races in the Struggle for Life* in 1859.

Travel as a touristic experience in the West developed during the 18th century in England, under the premise that it was an activity that improved the life and soul of the traveler. At the time, the "traveler" was specifically a white upper-class male because only they had the means and social status to conduct these expeditions. Thomas Cook, an English preacher, is often recognized as the creator of the modern tourism era for putting together packaged tours in the mid-19th century, many of them available to working-class people. These tours included trips to the countryside

and large cities of England, as well as abroad (Cook's first holiday abroad package was a tour to Germany in 1855). Those who traveled on Cook's trips were known as "Cookites." From this perspective, travel is a consequence of a uniquely Western dynamic. The Europeans "ventured to discover" and thus colonized much of the rest of the world. Thus, tourism and travel largely resulted from the success of European powers in grounding their presence in faraway places. There are common assumptions about travel from a Western perspective, including the supposition that modern tourism derives solely from the Western experience, and that travel is only associated with Western traditions.

A more comprehensive view, however, gives us a different explanation for the arrival of travel and tourism. Trade, conquest, and the quest for wealth and economic advantage are not the only reasons for traveling. There are multiple justifications for travel. Travel came about in the history of humanity long before the arrival of Western European colonizers to non-Western places. Archaeological evidence demonstrates extensive long-distance travel in the Western Hemisphere in pre-European times. Travel took place for many purposes other than colonization, and it did not occur only from the West to the non-West. For

instance, Japanese scholarship has focused on analyzing the propensity of Japanese citizens to travel and to purchase souvenirs as a result of centuries of traveling to pilgrimage centers. Believers in Islam have conducted religious pilgrimages to the city of Mecca (the *hajj*, considered one of the five pillars of the Islamic faith) in the form that it is conducted at the present time at least since the 7th century when the prophet Mohammed expanded and refined the pilgrimage. These trips, although not considered “packaged tours,” required the same level of organizational skill and need to anticipate and fulfill the needs of travelers. Another motivation for travel for many societies has been the pursuit of knowledge. Mary Helms, for example, has argued that the elite of pre-Columbian chiefdoms in Panama traveled great distances to obtain esoteric, often sacred, knowledge that enhanced their political power. Other scholars argue that the main motivations for traveling include the search for authenticity, or the search for exotica, the primitive, the different, the Other.

Anthropologists have traveled to distant places since the beginning of the development of anthropology as a discipline in the mid-19th century. Early on in the formation of the discipline, and as a reaction to “armchair” anthropology, traveling to a far away, “exotic” society was (and in some instances, continues to be) the essential rite of passage of fledgling anthropologists. However, the concrete act of traveling to the anthropologists’ destinations (and encountering other travelers and tourists on the way) was not considered an important aspect of the ethnographic experience until quite recently. For instance, the Belgium-born anthropologist Claude Lévi-Strauss, founder of structural anthropology and considered one of the most influential intellectuals of the 20th century, is credited with writing one of the best anthropological accounts of basic human societies, anthropology, and human thought (and a must-read travel book at the same time), *Tristes Tropiques*, originally published in 1955. In his book, Lévi-Strauss noted that adventure and travel are not part of the anthropological profession. He pointed out, “The fact that so much effort and

Source: © iStockphoto/EauClaire Media.

expenditure has to be wasted on reaching the object of our studies bestows no value on that aspect of our profession, and should be seen rather as its negative side.”

It was only in the 1970s that tourism and travel became subjects worthy of discussion in anthropology. Although many reasons have been given to explain this fact, two have gained wide acceptance. First, anthropologists argued that their experience and reasons for being in a distant place could not be compared to that of tourists and felt that in many instances they were being unfairly compared with the tourists they encountered in these faraway places. Secondly, and perhaps as a result of the first argument, anthropologists considered that tourism was not a serious enough subject to discuss intellectually and ethnographically. Although in practically every

ethnographic field site anthropologists encountered at least occasional tourists, they were perceived as an undesired nuisance and given scant or no attention. The presence of tourists intruded upon the pristine tradition-bound images envisioned for these communities.

In 1976, Valene Smith published the influential edited volume *Hosts and Guests: The Anthropology of Tourism*. This volume marked the beginning of a more serious interest in tourism and travel in anthropology. This scholarship has focused on the many dynamics of tourism, including the types of tourism and tourists. The travel industry acknowledges several types of tourism, such as ethnic, cultural, ecotourism, historical, recreational, alternative industry, and these days even guerrilla tourism, agrotourism, and cybertourism. Smith defined the tourist as “a temporarily leisured person who voluntarily visits a place away from home for the purpose of experiencing a change.” Thus, traveling carried out by tourists can be considered leisure travel, and it refers to voluntary displacement, which contrasts markedly with involuntary displacement due to political instability, wars, and forced relocation. Smith also developed a typology of tourists, dividing them into the explorer tourist, the elite tourist, unusual, massive, and charter tourists. Interestingly enough, as anthropologists had an elitist view toward tourists, elite tourists who prefer adventure and are concerned with having unusual and unique experiences with different cultures consider themselves “travelers,” and would not accept the label “tourist” placed on them.

Applied anthropologists have also focused their attention on other kinds of marginalized “travelers.” For example, a new phenomenon within the travel industry is the emergence of “transplant tourists.” This refers to the fact that the lack of donated organs for organ transplants in wealthy countries has produced an elaborate market for body parts (particularly kidneys) sold by people in the so-called third world. The newer trade involves the traveling of the kidney seller to his or her destination; the buyer sometimes provides airfare, accommodations, and even sightseeing tours.

In the 21st century, travel no longer involves only voluntary or involuntary displacement. Travel can also take place from the comfort (or discomfort) of one’s own home through virtual travel. One example of virtual travel is what tourism researchers call “cybertourism.” Cybertourism refers to travels carried

out by individuals or groups via the Internet. Interestingly, cybertourism breaks down the assumed premise of travel and tourism (leisure) versus everyday life (work). The dichotomy between work time (home/community) and leisure (away from home/community) can be overcome daily if one is so inclined. It is no longer necessary to wait for a vacation to break the cycle. The conventional categories of ordering of space and classifications fall by the wayside in the face of virtual worlds that can be visited by simply hitting a particular series of keys on a computer keyboard.

A group of mammals belonging to the order *Scandentia*, and included in a single family, the *Tupaiaidae*. They are endemic to the Indomalayan region, with a geographic range that extends from India to the Philippines. They reach their greatest diversity on the Southeast Asian island of Borneo, where ten of the twenty known species occur. Five genera of treeshrews are commonly recognized: *Tupaia*, *Anathana*, *Dendrogale*, *Urogale*, and *Ptilocercus*, of which *Tupaia* is the most diverse and best known.

Treeshrews are relatively small, squirrel-like mammals ranging in average body weight from less than 50g to about 300g. In many respects they retain anatomical features closely resembling the primitive eutherian mammalian condition. They have long, tapering muzzles with a moist glandular nose pad; relatively large eyes; small rounded hairless ears; a long slender body, covered in soft dense fur, which is

brown to olive in color, often with streaks or stripes; they have five short digits on their hands and feet, each bearing a well-developed claw; and a long, usually bushy tail, which is at least as long as the head and body in most species.

They primarily inhabit lowland and montane forest, but do occur in secondary forest, plantations, and gardens. Some species are predominantly arboreal, although they often descend to the forest floor, where they forage for invertebrates and small fruits. Other species are largely or exclusively terrestrial. All of the species are diurnal (i.e., active during the day), except for the nocturnal pen-tailed treeshrew (belonging to the genus *Ptilocercus*). They are active, agile, and fast-moving creatures who are skilled climbers and leapers in trees and dense undergrowth. Treeshrews are generally territorial, with a paired male and female defending a small home range. Adults build nests in trees, hollow logs, or underground burrows as sleeping sites. During the breeding season, females produce two offspring, who are born hairless and with their eyes closed. They have a remarkable “absentee” maternal care system in which the mother gives birth to her young in a separate nest from her own and only visits them every other day for a few minutes to nurse them.

Since their initial discovery in the late 18th century, their taxonomic position has proved problematic. Historically, they have been of interest to anthropologists because of their anatomical similarities and close

Geographical Distribution of Treeshrews in Asia

Common Treeshrew (*Tupaia glis*)

relationship to primates, and they have sometimes been included in the same order. They share several key specializations with primates, including enlarged forward-facing eyes enclosed by a complete bony ring, a reduction in the sense of smell, a specialized tooth-comb at the front of the lower jaw (as in lemurs and lorises), a relatively large brain, postcranial adaptations for arboreal climbing, ridged skin on the

palms and soles, and a small litter size. However, current authorities, while still acknowledging a close evolutionary link with primates, prefer to include them in their own order, but group them together with primates, bats, and flying lemurs or colugos in the superorder *Archonta*.

The fossil record for treeshrews is poorly known, and the earliest undoubted representatives come from the later Miocene (about 10 million years ago) of Indo-Pakistan and China.

TROPICAL RAIN FORESTS

About one third of the world's forests are tropical rain forests. They are the most ancient, diverse, complex, and productive ecosystems on the terrestrial surface of the Earth. Although they cover only about 6–8% of the land surface, they contain about half of all life, whether this is measured by the number of species (biological diversity) or organic weight (biomass). These forests form a discontinuous green belt around the equatorial regions of the planet, concentrated within ten degrees latitude north and south of the equator but extending in many areas to 23.5 degrees north and south within the tropical zone. About half of the world's tropical rain forest is in the Amazon region, and about 80% of that is in Brazil.

In tropical rain forests the average yearly temperature is 20–28°C or more, while the average yearly rainfall is above 2,000 mm. The climate is the closest to the optimal conditions for plant growth anywhere on Earth with its combination of high temperature, rainfall, and humidity. Consequently, this type of forest is the norm for plant growth on this planet, while every other kind of plant community is some

deviation in response to one or more kinds of stress such as lower rainfall or lower temperatures.

Water plays an extremely important role in the variation and dynamics of ecosystems in the tropical rain forest, as is implied by the designation *rain* forest. Rivers, streams, lakes, and swamps are found in many areas, and they are important to local people for water consumption, transportation, and trade, as well as for fish, birds, and other game for food.

The plant community of the tropical rain forest is characterized by its stature, luxuriance, and diversity. In mature forests there are giant trees, with few if any branches in their lower levels, standing like columns in a grand cathedral. Such forest is more or less stratified, with several layers that reflect vertical zonation in the microclimate and associated biota.

Animals are an important component of the structure, function, composition, and dynamics of these ecosystems. However, animals are relatively scarce. While their species diversity is high, their population density is low and individuals within a population are patchy in distribution. Furthermore, most animal species are arboreal, small in body size, solitary, camouflaged, and nocturnal. In addition, invertebrates such as ants and termites comprise most of the faunal biomass of the forest. The major exception to these generalizations about animals is the wild pig, which is terrestrial, large in body size and group size, diurnal, and noisy, and leaves obvious trails. Accordingly, in most tropical rain forests, wild pigs are usually the most important item by weight in the annual predation record for many indigenous hunters.

Since Europeans first started exploring tropical forests in the 15th century, this biome has probably attracted more attention than any other type of environment. It stimulates different reactions, depending on whether the observer's agenda is economic, political, religious, artistic, or scientific. Furthermore, the ambivalence of Western civilization toward the "jungle" is reflected in numerous binary oppositions like paradise/hell, rich/poor, harmony/chaos, peace/war, good/evil, and so on. That is, some people consider the forest to be a type of Eden, while for others it is Hades. This ambivalence is reflected in some local cultures as well. For example, as described by Colin Turnbull, in the Congo region of Africa, the Mbuti people who live inside the forest view it as affectionate and protective like parents, while Bantu neighbors dwelling on its margins consider it to be a dangerous place filled with evil spirits.

Such contradictory and contested images are also reflected in the scientific literature, although usually more subtly. The native or indigenous peoples of the forest have been viewed ambivalently by Western civilization as either “noble savages” (via Jean-Jacques Rousseau) or “bestial savages” (via Thomas Hobbes). In the ethnographic record of the Amazon, these positive and negative representations are exemplified respectively by Gerardo Reichel-Dolmatoff’s publications on the Desana and Napoleon Chagnon’s on the Yanomami. Usually more recent ethnographies are better balanced.

A rich source of reliable and detailed information about the natural history of the animals, plants, and ecosystems of the tropical rain forest is the local human community, especially indigenes. People who regularly engage in subsistence hunting, fishing, gathering, or farming in this ecosystem usually accumulate reliable and detailed knowledge of the species they seek for food in order to survive. What has been termed *traditional environmental knowledge* (TEK) can be critical in any attempts by outside agents to promote environmental conservation or economic development in tropical rain forests and other environments. Indeed, many such interventions have failed with dire social and environmental consequences because they ignored local cultures, TEK, and the like. Most, although not all, traditional indigenous societies have more often than not been sustainable, a fact proven by their continued existence as the descendants of the original inhabitants of an area over centuries or even millennia.

Forests survived in much of the tropics while humans inhabited them for centuries or even millennia, although in certain areas, such as those of some of the Maya in Central America and various islands in Polynesia, deforestation occurred already in prehistory. For the most part, however, deforestation in places like the Amazon is a recent phenomenon of the last few decades and is related to the introduction of

Source: © iStockphoto/Mark Huntington.

alien technologies and economies as well as regional, national, and international politics.

Only since the 1960s has the rate of deforestation in the tropics become alarming. Through space and over time, different combinations of factors contribute to deforestation. These include cattle ranching in tropical America, government colonization schemes in the Brazilian Amazon and the Indonesian outer islands, gold mining in Brazil, oil extraction in Ecuador and Peru, plantation monocrops like rubber trees in South and Southeast Asia, and hydroelectric dams in various areas.

Cultural diversity and biological diversity are both extraordinarily high in tropical rain forests, a coincidence that is called the diversity principle. (Both types of diversity decrease progressively from the equator toward the poles.) Conservationists identify

Brazil, Congo, and Indonesia as among the megadiversity countries because of their high biodiversity. Such countries contain high cultural and linguistic diversity as well. They are also the hot spots (endangered areas) for both tropical rain forests and indigenous cultures. These two endangered phenomena are interrelated and cannot be considered in isolation from each other. Moreover, traditional environmental knowledge as well as land and resource use, management, and conservation practices are indispensable to consider in countering the threats to these cultures and to their forest habitats from both the human rights and environmentalist perspectives.

The awesome cultures and environments of the tropical rain forests have far too much intrinsic value to sacrifice merely for the material “progress” of the contemporary consumer society. The latter is predicated on infinite growth on a finite base, which is an impossibility. Such ecocidal societies are destined to self-destruct sooner rather than later. The tropical rain forest, the people who consider it their homeland, and their cultures and religions deserve to be appreciated and respected on their own terms. Tropical rain forests are the last refuges for biological and cultural diversity on Earth, and diversity is indispensable for continued adaptation and future adaptability.

The city of Troy, situated on the northwest coast of modern Turkey, occupies a special place in Western culture. The story of the sack of Troy told by Homer was considered history in antiquity, then myth, then imaginative poetry, and then history again. It provided a major theme for Western art throughout the millennia; created the archetype for the “hero”; and created a view of war, honor, fame, and aggression that many have blamed for the continued glorification of warfare in the West. During the late 19th century, the story of Troy showed something else: that myth can contain kernels of truth. The businessman-turned-archaeologist Heinrich Schliemann began to excavate a site tentatively identified as Troy. His stunning discoveries appealed to the imagination of many generations. After his death, excavations continued under W. Dörpfeld, in his turn succeeded by C. W. Blegen. Activities ceased after 1938. After a hiatus of 50 years, excavations resumed in 1988. New finds conducted on a larger scale continue to provide important information.

Troy in Myth and Epic

Troy is best known as the city attacked by the Greeks to regain Helen, the wife of the Achaean king Menelaos, after she was kidnapped by a Trojan prince. The *Iliad* tells the story of the last ten days of the battle for Troy, or Ilion—hence “Iliad”—and the decisive battle between another Trojan prince, Hector, and his Achaean or Greek counterpart, Achilles. The *Odyssey* retells the story of the return home of one of the other warriors, Odysseus. The story of the preliminaries to the conquest and the return of Odysseus are set in a timeless world, thought to provide a much-retold and therefore not very accurate description of early Bronze Age Greece, when writing, to our knowledge, was not used to transmit historical events. If the *Iliad* and *Odyssey* tell of true events, the poems must have been transmitted orally over a long period of time. The investigation of their oral origins during the late 18th century marks the beginning of philological research on “orality,” laying the foundation for modern research on orality, oral performance, social memory, and the role of oral transmission among nonliterate populations.

Troy in Antiquity

Troy, also known under its modern name of Hissarlik (or Hisarlik), and sometimes identified with the city called “Wilusa” by the Hittites, is situated in north-west Turkey, or Anatolia. During the second millennium BCE, Troy was about a mile away from the coast and provided protection for trading ships sailing into the Black Sea. The south wind, necessary to sail into the Black Sea, only blows during the spring and the fall, forcing ships to wait. Homer calls the city “Windy Troy.” It was only around the first century BCE that sailors learned to sail ships against the wind. A land trading route linking Asia Minor with Europe also led through Troy. Throughout time, Troy was an important site for visitors who exploited its fame for their own purposes.

The Greeks believed that the Trojan War, as told in the Homeric epics, really did take place. The poems were performed and reperformed, and Greek literature borrowed its heroes, plots, and language. The Greek historian Herodotus (late fifth century BCE) explained the Persian wars as a continuation of the east/west conflict that had existed since Homeric times, a trope that was borrowed again and again. When Alexander the Great, who considered himself a descendant of Achilles, set off to conquer the East ca. 335 BCE, he stopped at Troy and made offerings at the temple of Athena. In 192 BCE, Antiochus III, the Seleucid king of Asia Minor, stopped at the same temple before attempting his invasion of Greece.

But the Greeks were not the only ones to claim the city of Troy as theirs: two years after Antiochus III, the Roman Consul Scipio visited the temple on his way to subdue Antiochus. The inhabitants of Troy, aware of its historical significance, happily obliged and received benefits from all visitors, such as tax exemptions and financial support for temple construction. The Roman connection is somewhat tenuous: some aristocratic families claimed descent from the Trojans. When the city was destroyed, they believed, some Trojans made their way to Italy via Carthage on the coast of North Africa. The hero, Aeneas, scorned the offer of the Queen of Carthage to share her kingdom: he claimed to be on a holy mission to find new land for his followers “in the west.” Thus, the story of the Trojan war provided a more noble excuse for Rome’s continued conflict and final destruction of Carthage, a conflict caused by trade rivalry. Caesar and his descendants claimed direct descent from Aeneas to

justify their conquests in North Africa and Asia Minor (Turkey and beyond).

Although the Homeric epics were lost in the West during the early and late Middle Ages, the story of the sack of Troy was not. Theodoric the Great (453–526), king of the Ostrogoths, claimed some Trojans had fled up the valley of the Danube and settled among the Franks. Trojan descent was widely claimed by German nobles and provided a (lame) excuse for the sack of Constantinople during the Fourth Crusade (1204). Sultan Mehmed II, the Ottoman conqueror of Constantinople in 1453, recognized Troy’s symbolic power in his turn: he visited the fabled ruins, listened to a recitation of Homer, and announced that his conquest of Constantinople was in revenge for the sack of Troy by the Greeks two thousand years earlier.

During the Renaissance, Greek literature was reintroduced into the West and depictions of Homeric heroes and battles were rekindled in poetry and pictorial art. The fascination with the story grew, and during the Age of Romanticism the demands to free Greece from the Ottoman occupier gained force.

First Excavations

The Romantic view of Troy also inspired Heinrich Schliemann, who began excavations in 1870 on a site called His(s)arlik. Several trenches were dug through the man-made hill, revealing several layers of a city. One layer showed signs of burning, leading Schliemann to identify it as the Troy destroyed by the Greeks. Schliemann was the first to apply a technique called “stratigraphy” to conduct his excavations. Schliemann recognized 7 layers, with I (in Roman numerals) as the earliest one. This number was increased to nine by his successors, with several subdivisions indicated by letters of the alphabet. Excavation of such a long-occupied site—evidence recently has come to light that the site was occupied since the third millennium BC—is complex; old building materials were frequently used to construct new buildings, while the Romans razed the top of the hill for the temples whose construction they funded. Schliemann discovered the so-called “Treasure of King Priam,” a hoard of gold jewelry. He shipped it to Germany, to the dismay of the Turkish government. After World War II the treasure was lost—only to reemerge in the mid-1990s in the Pushkin Museum in Moscow.

Current Excavations

Excavations resumed in 1988 under the joint leadership of M. Korfmann of the University of Tübingen and Brian Rose of the University of Cincinnati. Scholars of many other disciplines and countries participate as well. A problem in archaeology of the ancient world is that sites become the “property” of a country or a university, and as a result, publications appear in the corresponding language: in French (Olympia), German (Troy), or English (Athens). An added difficulty is that customarily, archaeological field reports are slow to appear. However, the team at Hisarlik is conscientious about rapid publication—in German.

The new (contested) finds show that after the city was destroyed during the 12th century, it was subsequently inhabited by Greeks—much earlier than commonly believed. They also show that Troy was an important center of political power in the second millennium BC.

TSWANA BANTU

The term “Tswana Bantu” refers to both ethnic peoples and a language. The Tswana Bantu population, related to the Sotho, divide themselves into subgroups (lineages): the *Hurutshe*, *Gwaketse*, *Kgalagadi*, *Kgatha*, *Kwena*, *Malete*, *Ngwato*, *Rolong*, *Tawana*, *Thlaping*, and *Tlokwa*. The country of Botswana (which literally means “Land of the Tswana”) bears the name of the Tswana, but only a small portion of

them are citizens there (approximately 800,000 to 1 million), whereas most of the Tswana Bantu speakers (2.5 to 3 million) reside in Bophutatswana (“The Place Where Tswana Gather”) in the northeast of South Africa. Less than 25,000 Tswana Bantu reside in Namibia; perhaps 25,000 to 30,000 live in Zimbabwe.

According to its technical linguistic designation, Tswana (Setswana) belongs to the Bantu subbranch of the Niger-Kordofanian language family. It is closely related to Western Sotho and is sometimes referred to as such. English is the official language of Botswana; however, more than 80% of the population speak the Setswana (Tswana) dialect. Furthermore, Setswana is the language of the educational system and of the media. This does not pose a problem for those who speak other dialects of Tswana, for all of the dialects are mutually intelligible. Tswana was orally transmitted until the 1800s when British Protestant ministers (seeking Tswana Bantu converts) translated the Bible.

The issue of whether Sotho-Bantu speaking populations (such as the Tswana) came originally from northwest or eastern Africa is debatable, and a precise date is not available as to their arrival in southern regions of the African continent, nor is the actual reason for a mass migration known. However, one motivation may have been the gradual desertification of sub-Saharan Africa beginning approximately 10,000 to 8,000 years ago. This may have caused Bantu populations to leave hypothetical homelands in successive waves. Only one thing is known with certainty: by 1600 the Tswana Bantu speakers inhabited certain regions of present-day Botswana, South Africa, Namibia, and Zimbabwe.

At that time, they lived in major towns with satellite villages and practiced swidden agriculture of domesticated millet, sorghum, beans, melons, and *morama* (a tuber). The Tswana also continued to hunt, fish, and gather. Traditional drinks include palm wine and homemade sorghum beer. The measure of wealth was cattle that were used to pay debts and contract political alliances, and upon marriage cattle comprised payments to the bride’s family; thus cattle were imbued with symbolic value. The breeding and herding of cattle was the responsibility of boys and men who also raised sheep and goats. This work was forbidden to women. Men also raised the timber frames of houses, cleared new fields, and assisted the women and children in planting, weeding, and harvesting crops. All objects of skin, wood, bone, and metal were made

by men. This division of labor persists to the present time, except that after oxen were used as draught animals men began to plough. Today women no longer are forbidden to raise cattle; however, the herding and milking of cattle are still done by males.

In traditional households, women were responsible for children, tilling the fields, building huts and granaries, thatching roofs, cooking food, making beer, and raising fowl. Women made the pottery. However, separating subsistence activities into male and female spheres is problematic, as classic studies of the Tswana illustrate, because many tasks were shared by young and old, wives and husbands, brothers and sisters, as well as relatives of near and distant kin. Men and women made baskets, but these men and women belonged to certain specialist lineages. Iron and copper-smith families, traditional religious healers, and those specializing in the art of pottery also adhered to hereditary precedents. Knowledge of these particular trades was considered to be a sacred trust that was guarded zealously against all usurpers; it was to be transmitted only from elder to apprenticed youth of certain hereditary lineages (both male and female).

Today, however, globalization makes such ancient crafts nearly obsolete. For example, though traditional skills were transferred to handcrafted furniture production and dressmaking in the 1950s and 1960s, by the 1970s, mass-produced furniture and mass-produced clothing made such skills unnecessary. Sometimes the only viable subsistence strategy is to leave the farming village to earn money as domestic and industrial labor. Many young people move to urban centers in search of work to assist hard-pressed rural families who struggle against drought and the poverty that attends it.

From the 1800s to the 1900s, the British and Dutch divided Tswana lands between them, now respectively called the sovereign states of Botswana and South Africa. Those Tswana who lived in (Reformed Dutch) South Africa were affected by Dutch racial policy called *apartheid*, the policy that created Bophutetswana, a nonsovereign “Black” country within the “White nation of South Africa.” Those Tswana who lived in Botswana were British subjects and under British “self-rule” policy that encouraged chieftdom as long as the “chief” had the approval of the British colonial administration. The hereditary chief’s power was not absolute but subject to the scrutiny of advisers and council. Often more able and elderly tribal leaders threatened British hegemony, causing the British to

appoint a Tswana leader more amenable to British demands, someone who would readily collect taxes for the British and someone who would convince Tswana youth to work for the British for substandard wages under conditions of slavery, separated by geography and custom from white compatriots. Today, though apartheid has been outlawed, indigenous populations of Africa, such as Tswana, continue to fight against landed and monied proponents of apartheid, an entrenched hegemony difficult to either identify or eradicate.

As the Tswana Bantu have been economically colonized, so too have the Tswana sustained incursion of Christian ideology. Various European religionists sought to impose their religious beliefs upon Tswana Bantu. In the 1800s, British rule allowed the influx of many Christian denominations including Congregationalists (the London Mission Society), the Dutch Reformed Church, Methodists, Lutherans, Anglicans, and Roman Catholics, all of whom founded missions among the Tswana populations. However, despite their diligent attempts to convert the Tswana tribes, a recent Botswana government survey suggests that to a great extent the Tswana have retained ancient religious practices, such as the veneration of the ancestors and a belief in the efficacy of magic spells. According to this survey, as many as 50% of the Tswana may practice traditional religion. The next largest religious group is Roman Catholic. Various Protestant sects divide the remainder of the Tswana among themselves. Women are generally more involved with evangelical brands of Christianity than men, who often espouse indifference to it. Another complication is that those who avow Christianity and who regularly attend Christian services of various denominations may also venerate the ancestors with prescribed sacrifices and ceremonials. These same people may also continue to consult traditional religious specialists (shamans) and healers when modern medical practices fail, or when the cost of Western medical care is prohibitive.

The most eminent anthropologist of Tswana culture was Isaac Schapera (1905–2003). Schapera was research assistant to Bronislaw Malinowski while fulfilling Ph.D. requirements at the London School of Economics in the 1920s. He also fulfilled the position of professor at the University of Cape-town from 1935 to 1950, dedicating his life to the documentation of Tswana Bantu history, law, art, language, literature, custom, and religion. Many

contemporary anthropologists owe him gratitude for his pioneering work among the Tswana.

TURNBULL, COLIN M. (1924–1994)

Colin M. Turnbull was born in Harrow, England and educated at Magdalen College, Oxford. After serving in World War II in the British Royal Navy, he returned to Oxford and finished his education. Turnbull ultimately received his Ph.D. from Oxford in 1964. He

also studied in India under Sri Anandamayl Ma and Sri Aurobindo (1949 and 1951), and then went to Africa where he was introduced to the Mbuti Pygmies.

The Mbuti Pygmies became a lifelong passion for Turnbull. As the African Ethnology curator for the American Museum of Natural History, he was in a unique position to return to the Ituri Forest in Africa to live with and research the region and its people. From his years of studying the Mbuti Pygmies, Turnbull produced his seminal book, *The Forest People* (1961). This very personal analysis of the Mbuti Pygmies and their culture was a unique view of a very rich and complex society that was often looked down upon by other peoples in the area and the world. Turnbull brought to the world stage all that was good and positive about the Pygmy culture and society. Through their songs and rituals, these pygmies showed a deep love for life in the African forest. Turnbull also collected the songs of the Mbuti Pygmies and presented them in collections for the American Museum of Natural History. The love and esteem that he felt for the Mbuti Pygmies was immense, and he would see their life as a metaphor

for his own life. Throughout his career, Turnbull wrote many other books about the Mbuti Pygmies of the Ituri Forrest and the conditions of the African people.

In 1965, Turnbull returned to Africa to study its peoples, but this time he did not go to study the Mbuti Pygmies. Instead, he studied the Ik of Uganda. This was a people displaced by the civil strife between Uganda and Kenya, as well as the development of a national wildlife reserve on their traditional hunting ground. Unlike the Mbuti Pygmies, the Ik were a people that because of these circumstances, had reduced their regard for each other to the point where they were immune to the suffering of their family members and other members of their tribe. Turnbull saw this and wrote that the society was not one of lofty values, but that this specific society and its culture were determined by the conditions that the people lived in at that

Source: Courtesy, Avery Research Center.

time. Unlike the rave reviews that *The Forest People* received, *The Mountain People* (1973) was severely criticized by many anthropological scholars. Some suggested that it was shoddy scholarship and that the book should be banned. Yet, others appreciated the depth to which Turnbull could understand the life and the conditions of the Ik.

Besides working as a curator at the American Museum of Natural History, Turnbull held professorships at a number of universities, including Virginia Commonwealth University and George Washington University. In 1982, he turned down tenure at George Washington University in order to devote his time to caring for his long-time partner Joe Towles.

Turnbull traveled extensively and studied various religions and cultures. He studied Hindu religions in India, the African culture, Samoan culture, and ultimately was ordained as a Tibetan Buddhist monk by the Dalai Lama. He became known as Lobsong Rigdol. In 1994, Colin M. Turnbull died in Lancaster County, Virginia.

TURNER, EDITH (1921–)

As one of the most important proponents of humanistic approaches to anthropology, Edith Turner has influenced how anthropologists think about women's roles within the discipline and how anthropologists write. Her first solo authored book, *The Spirit and the Drum*, originally written in the 1950s but not published until 1987, cannot easily be located in postmodern and feminist categorizations. In anticipation of postmodernist debates in anthropology, this deeply personal account of her years with the Ndembu of southern Africa challenged anthropologists to rethink both the fieldwork experience and ethnographic writing.

For most of Turner's career, she worked in collaboration with and was often overshadowed by her husband Victor Turner, who she met during World War II and with whom she shared a lifelong love of literature. After the war ended, while her husband attended the University College of London and then University of Manchester, Turner began an informal anthropological education. At the same time, she cared for their children, she attended lectures at Manchester, read anthropological theory and ethnography, and discussed the profession with her husband, his students, his colleagues, and his professors.

When her husband was awarded a Rhodes-Livingstone grant to conduct ethnographic research, Turner went into the field with their three children and collected data, writing her own field notes on rituals, ceremonies, and women's life, typing her husband's field notes, and serving as photographer on the project. Although their colleagues were aware that Turner and her husband collaborated in all aspects of research and writing, they rarely shared bylines. To a great extent, she put aside her literary and anthropological goals in order to support her husband's career and raise their children.

Not until the 1970s was Turner formally recognized for her anthropological contributions. In 1974 she was one of the founding members of the Society for Humanistic Anthropology, and in 1978 she shared authorship with her husband on the volume *Image and Pilgrimage in Christian Culture: Anthropological Perspectives*. In 1980, Turner was awarded a Master of Arts degree in English, despite never having earned a Bachelor's degree. In 1983, she was appointed Lecturer of Anthropology at the University of Virginia, where her performative approach to teaching has left an indelibly positive influence on her students.

Since her husband's untimely death in 1983, any doubts about Turner's capabilities as a fieldworker, theoretician, and anthropological writer have been laid to rest. At an age when most anthropologists are retiring, she has produced an oeuvre over the last 20 years that most anthropologists never accomplish. Aside from editing the journal *Anthropology and Humanism*, she conducted research in Zambia, Alaska, and Ireland, focusing on traditional healing, initiation and other rituals, and symbolic experience. In addition to a respectable number of scholarly articles, she has written three important ethnographic monographs: *The Spirit and the Drum*, *Experiencing Ritual* (1992), in which she returned to Zambia after

thirty years to update her research on spiritual processes and theories of pilgrimage, and *The Hands Feel It* (1996), which is about the spiritual beliefs and healing practices of the Inupiat of northern Alaska.

TYLOR, EDWARD BURNETT (1832–1917)

Edward B. Tylor, founder of the study and curriculum of anthropology, is considered to be the first cultural evolutionist anthropologist and the father of the science of anthropology.

Tylor was born the son of Quakers on October 2, 1832 in London, England. He attended school at Tottenham, but due to poor health withdrew to travel to North America, where in Mexico he befriended ethnologist Henry Christy. Tylor was fascinated by anthropology and the prehistoric remains in Mexico, and he systematically investigated the artifacts and cultures of the peoples who had inhabited the area. His investigations evolved from incidental ethnography to sophisticated ethnology. Returning to England, he married Anna Fox, attended meetings of the Ethnological Society of London, and in 1861 published *Anahuac*, an account of his Mexican journey that contains anthropological commentary. In 1865 he published *Researches Into the Early History of Mankind* and *The Development of Civilization* to begin an active study of anthropology highlighted by his masterpieces, *Primitive Culture: Researches Into the Development of Mythology, Philosophy, Religion, Art and Custom* (1871), which is one of the major works of the 19th century, and *Anthropology: An Introduction to the Study of Man and Civilization* (1881), which still holds relevance today.

Tylor became a Fellow of the Royal Society in 1871. He received a Doctor of Civil Laws degree at

Source: © Bettmann/CORBIS.

Oxford (1875), was appointed Keeper of the University Museum (1883), presided over the newly formed Anthropological Section of the British Association (1884) and the Royal Anthropological Institute, was given a Readership in Anthropology (1884), became Oxford's first professor of Anthropology (1896), received an Honorary Fellowship at Balliol (1903), retired as Emeritus Professor (1909), received a knighthood (1912), and died on January 2, 1917.

Tylor's contributions to the science of anthropology are historic, especially his analysis of small-scale society and the relationship between culture and mentality, and his work on the evolution of culture and the religion of animism (omnipresent spiritual life in all organic living things). Establishing a taxonomy or lexicon of anthropological concepts and a basic curriculum in anthropology studies were his academic goals and accomplishments. His basic curriculum is the prototype for the undergraduate degree in anthropology.

The principle of cultural evolution threaded his work: culture and civilization evolve along unilinear timelines from small scale (“primitive” or “savagery”) to large scale (“civilization”) in opposition to the theory of “cultural degeneration.” His work took to task religious orthodoxy and divine inspiration of religious belief. Tylor labored to apply the scientific method to the study of humanity and crafted his theory of systematic evolution, describing the development of all societies along a single timeline or progressive pattern from a single natural state: human development progresses from “savagery” to “civilization.”

Tylor asserted that culture had been created by intelligent men and had evolved into civilization, a “developmentalism” enveloped in comparative

methodology. Interest in his works continues, and anthropologists subscribe to the theory that human culture evolves in relationship to physical evolution.

Ubirr lies in Kakadu National Park in Arnhem Land, in the Northern Territory of Australia. Kakadu encompasses nearly 5 million acres of land, most of which is inaccessible by car. Darwin, the closest city of any size, is a 12-hour drive from Ubirr. Ubirr first appears to be a rather chaotic collection of rock art. Australian Aborigines have been painting and repainting the walls of Ubirr for thousands of years. In fact, Aborigines can boast the longest continually practiced artistic tradition in the world. Tribes of Aboriginal hunters and gatherers established the site over 20,000 years ago for its desirable location. The site was central to a large variety of plant and animal resources from the East Alligator River, the Nadab floodplain, marshes, nearby woods, and the surrounding rocky outcrops, making the area very valuable. The rock art at Ubirr and other sites in the area has been divided into three distinct periods based on the content of the pictures and the styles in which they were painted: Pre-Estuarine (ca. 40000–6000 BC), Estuarine (ca. 6000 BC–500 AD), and Fresh Water (500 AD to the present).

The rock art at Ubirr was created using a variety of materials and methods. While red ochre was the most prominently used pigment, there are also yellow, white, and brown paintings. In the more recent recorded past, Aborigines created the paintings using brushes made from feathers, bark, or chewing the ends of sticks. It is assumed these same techniques were used in the more distant past as well.

Scholars have identified 11 main art styles at Ubirr, spread across the three time periods. During the Pre-Estuarine period, the climate was drier and the sea level lower. Art at this time consisted of large naturalistic

humans and animals, object prints, which are hands or other objects dipped in paint and pressed on the rock surface, dynamic figures, simple figures, and yam figures. Dynamic figures are small, detailed drawings of humans and animals. The human figures are generally animated, involved in some activity. Simple figures are stylized images drawn with a single thick line. Many are shown with boomerangs. The yam figures are human or animal forms blended with wild yams. The yam is usually the head of the figure.

The Estuarine Period began when flooding filled river valleys and created mangrove swamps. Crocodiles, barramundi, and catfish first appear in the landscape and in the rock art during this period. Beeswax art also first makes an appearance. Beeswax was applied to the rock walls to create simple designs and human figures. The x-ray descriptive style portrays both the external and internal structure of humans, animals, or inanimate objects.

During the Fresh Water Period, freshwater billabongs and swamps replaced saltwater systems. The paintings reflect new resources attracted to the area. Waterlilies, geese, and human figures carrying goose feather objects or goose spears were depicted. There are two styles of Fresh Water art: contact art and x-ray decorative style. The x-ray decorative style evolved from the earlier x-ray descriptive style. Some artists appear to have lost interest in the detail of internal organs and simply divided the figures they painted decoratively. Contemporary artists use both forms of x-ray art. Contact art records the initial contact of the natives with outsiders, both Chinese and European.

There are three main art sites at Ubirr: the Main Gallery, the Namarrgarn Sisters, and the Rainbow Serpent. The Main Gallery is a large rock overhang where family groups made camp for thousands of

years. Figures were regularly painted on the back wall of the shelter. The Namarrgarn Sisters at Ubirr are represented as crocodiles and the illustrations tell a story shared with children to explain what crocodiles are and why they are dangerous. This story is part of a longer cycle of stories learned over a lifetime. An individual is told additional stories as he or she passes through the stages of life, and may one day be given the responsibility of passing the stories on to others. The Rainbow Serpents are powerful ancestors from the Creation period. They are among the oldest artistic symbols used and can be found throughout the world even though their stories vary according to the environment, social, and cultural traditions of the location. In Kakadu, the Rainbow Serpent is described as an all powerful, ever-present “boss lady” who rests in quiet waterways. Rainbow serpents at Ubirr are almost always portrayed as females who are associated with water, will eat anything but flying foxes, and hate loud noises. When disturbed, they may cause a flood or an earthquake.

The rock art at Ubirr illustrates stories traditionally passed down through the generations to teach the young members of the tribe the “laws,” or moral and ethical codes of their culture. Sadly, many Aboriginal tribes and languages no longer exist, so the stories associated with much of the art are lost to us forever.

UNAMUNO, MIGUEL DE (1864–1936)

Spanish novelist and philosopher Miguel de Unamuno is best known for his conception of the “tragic sense of life,” but was also a noted man of letters. Born in the Spanish Basque city of Bilbao, Unamuno studied philosophy and classics in the Spanish capital at the University of Madrid. In 1891, Unamuno was awarded a professorship in Salamanca, where he taught classics. He was later named rector of the University of Salamanca, and although the turbulent politics of Spain led to his having to give up the post between 1924 and 1930, he reassumed it upon his return to Spain in 1930. Unamuno also served a

brief stint as a politician, as an independent republican deputy in the Spanish constituent assembly, the Cortes.

Unamuno’s novels center around broadly “existential” themes, just as his philosophical work focuses on the problems pertaining to the human condition. The human being in Unamuno’s novel must labor and toil under the shadow of death. Like condemned men to the gallows who have not been told the date of their execution, we live with death as a constant companion—one which we can neither embrace nor elude. From the tension that comes from being caught somewhere in the middle of life and death emerges a “tragic sense of life,” a theme that echoes throughout his

writings. Unamuno's works revolve around the trials and sufferings of individuals, rather than broader social themes. The characters in Unamuno's novels do not "stand" for anything greater or larger than themselves, except insofar as they are exemplars of the tragic sense of life itself.

Unamuno pursued the Socratic ideal of the philosopher as a "stinging gadfly" that inspires the large and indolent "horse" of society to appropriate action. Despite his tragic sense of life, Unamuno was fundamentally constructive in his approach to the real problems of daily existence. Rather than encourage him to wallow in despair, Unamuno's tragic sense inspired him to use his talents and his reason to improve his lot and that of those around him.

Also crucial to Unamuno's worldview is the tension between reason and faith. Unamuno was both a passionate Roman Catholic, and readily acknowledged the difficulties of living a life of reason that nonetheless recognized and even embraced the need for faith as an integral part of a full and meaningful life. Unamuno's dedication to the Church may well have had its source in his belief in the necessity of commitment to an ideal—that a good life was one lived in accordance with some ideal. In this Unamuno personally exemplified what he saw as the two sides of the Spanish temperament. Unamuno described Spaniards as at once Don Quixote and Sancho Panza, idealistic and willing to suffer loss in the pursuit of an ideal, yet also at times intolerant and crassly commercial.

During the Spanish Civil War, Unamuno's early enthusiasm for the nationalists waned, causing him to lose his rectorship at the University of Salamanca. True to his ideas about commitment, truth, and decency, Unamuno refused to change his stance and died while under house arrest in 1936.

UNIFORMITARIANISM

Uniformitarianism is among the primary doctrines in the science of geology. It states that all processes that can be seen sculpting the Earth today have operated throughout geologic time and will continue to operate in the future. This also lends itself to the idea of "gradualism," whereby change in our world is slow and gradual because that is what we observe on Earth today. We see lakes and streams that slowly deposit centimeters of silt and mud per year, and the casual erosion by the Colorado River that has carved so deeply into the sandstones of Arizona created a scar that lays bare billions of years of depositional history. Using the principle of uniformitarianism, geologists can gain great insights into the formation of very old rock. By comparative analysis of the patterns and internal structures of old rocks and the structures of newly forming rocks in particular environments, geologists can safely infer which types of rock form in different environments.

The shifting dunes that populate the deserts in the more arid regions of the globe are products of wind blown sand. When analyzed, the rock particles that are incorporated in the microstructure of the dune have a characteristic form and dimension. When rocks of a similar structure are located beneath a modern temperate forest, geologists can deduce that when those rocks were deposited, the environment in which they were deposited was very dry, hot, and vastly different from the present ambience. The principle of uniformitarianism suggests that because the rock that is currently forming in the dune shares a very distinctive structure with older previously formed rocks, the two rocks are related because they seemed to have formed in the exact same manner. This illustrates a common occurrence in modern geology: a current overlaid environment floored by rock layers that were deposited in radically different climates. In most situations these observations can be explained using the principle of uniformitarianism. For hundreds of years geologists have concluded that the principal holds true, and it continues to be a useful reasoning tool when deciphering geological puzzles.

Originally dubbed the Huttonian theory by James Hutton (1727–1797), and occasionally referred to as "actualism," uniformitarianism is a cornerstone of geology and contributes to many other sciences. In many branches of science, initial logical assumptions

must be agreed upon and understood before anything novel can be gleaned from research. Uniformitarianism is one of geology's essential assumptions. Hutton, a Scottish farmer and physician, is considered to be the founder of modern geologic thought and was the first to recognize and describe the cyclic processes of the Earth. At his home in Scotland, Hutton was impressed by the sedimentary layers of sandstone that were once laid down horizontally (formally called the "Law of original horizontality"), but were now thrust up vertically and capped with younger layers perpendicular to the vertical beds. He realized that the cycle of uplift, erosion, deposition, solidification into rock, and finally uplift again was visible in the Earth's layers and the whole of the cycle could be deduced from looking at present rock strata (individual rock layers that represent specific depositional events). In 1795 he published his two-volume work entitled *Theory of the Earth, with Proofs and Illustrations*, which contained the first real counter-theory to the previous dogma of Catastrophism. There is, he wrote "no vestige of a beginning, no prospect of an end" to the geologic cycles of Earth. Hutton's visionary and controversial insights into geologic processes and the rock record allowed many later geologists to accredit him for being the first to conceive of the principal of uniformitarianism, which laid the groundwork for future scientists to make a profound discovery that changed the face of geology permanently: the earth is extremely old. However, this concept drastically altered the current perception of biblical occurrences guiding geology, which, up until then, were considered responsible for all land features. Uniformitarianism's paradigm altering agenda wasn't clearly an accepted doctrine until the 19th century. Expanding on Hutton's principals, a fellow Scotsman, John Playfair, in his *Illustrations of the Huttonian Theory* (1802), made little headway competing against the upheld religious dogma. For religious scholars, the suggestion that geological history reached much further back than what was allowed for in the Bible was absurd. It is clear that the process of erosion is painstakingly slow and, if the principle of uniformitarianism holds, the enormous amount of time needed for rock to be uplifted, eroded, formed into rock again, and be lifted up forming mountains is nearly incomprehensible. Since its initial rationalization, the principal of uniformitarianism has been fought at every turn; however, it remains today as a guide for all geologic explanations and reasoning.

After Hutton's initial description of the principle, Charles Lyell (1797–1875) formulated it into the doctrine as it is known today. Lyell, a British lawyer and honored geologist, was, perhaps, the greatest advocate of uniformitarianism. His work in the then-budding field of geology propelled this principle to become a mainstay of geologic reasoning, dislodging the preeminent theory of the day: Catastrophism. His magnum opus, *Principles of Geology*, in which his gradualist, uniformitarianist views on geology were ostentatiously exhibited, was accepted and used as a sounding board for many new scientists such as Charles Darwin and Alfred Russel Wallace. At the time, however, many of Lyell's contemporaries, such as the polymathic William Whewell, disliked the idea of a uniform and consistent world. Whewell's defense of catastrophism in light of uniformitarianism was grounded in a more empirical stance from such evidence as the fossil record. Even the earliest studies of the fossil record revealed gaps in the types and numbers of species that lived at different layers of strata. This insight was not perfectly in line with Lyell's work and as a result of Whewell's counterarguments, Lyell was forced to constantly defend and clarify his theory. Through his struggle, Lyell's work decidedly erected the scaffold from which modern geology was constructed. From this, many future scientists built upon this principle, and combined its logic with their own sciences' philosophy to form other hypothesizes that established many new and creative approaches to scientific quandaries.

The English anthropologist Sir Edward Burnett Tylor (1832–1917) also utilized the principle of uniformitarianism in expressing his hypothesis that civilized society had evolved through nonsupernatural processes from "savage" societies similar to those encountered throughout many parts of the globe. In his book, *Primitive Religion*, he explores the notion that human cultures, and especially religions, are products of natural, regular, progressive and uninterrupted expansion of the mental capacities of *Homo sapiens*. This apparent progression could be seen as a reflection of uniformitarianism and Tylor used this comparison to further his notion as a reasonable and sound science.

Although the principals of uniformitarianism and catastrophism have been at odds for centuries, with many champions on both sides that fought for a spectrum of reasons, the principle of uniformitarianism survives and is still taught today in modern geology

classes around the world. Usually the tendency is to teach a synthesis of the two principals because it is clear now that both have had an enormous impact on, not only the appearance of the Earth's surface, but also on the very inhabitants that occupy it.

UNITED NATIONS AND ANTHROPOLOGY

When the United States decided to reverse the Iraqi invasion of Kuwait, it did not act unilaterally. It turned to the United Nations (UN) Security Council.

When the Security Council sought to learn the extent of chemical, biological, and nuclear arms in Iraq, it did not rely on U.S. forces. It dispatched inspectors from the International Atomic Energy Agency (IAEA).

When the international community sought to maintain the suspension of combat in Bosnia, it did not rely only on national efforts. It sent in peacekeeping units under the auspices of the UN and North Atlantic Treaty Organization (NATO).

When states liberalized trade in services and strengthened intellectual property protection in the Uruguay Round, they were not content to draft rules. They created the World Trade Organization (WTO), and a highly institutionalized dispute settlement mechanism.

Formal international organizations are prominent participants in many critical episodes in international politics. Examples in addition to those above include the following: Security Council sanctions on Libya, IAEA inspectors in North Korea, UN peacekeepers in the Middle East, and so forth. The UN secretary-general's 1992 Agenda for Peace establishes an even broader range of current and proposed UN functions

in situations of international conflict: fact finding, early warning, and preventive deployment; mediation, adjudication, and other forms of dispute resolution; peacekeeping; sanctions and military force; impartial humanitarian assistance; and postconflict rebuilding. But international organization influence is not confined to dramatic interventions such as these. On an ongoing basis, formal organizations help manage many significant areas of interstate relations, from global health policy (the World Health Organization or WHO) to European security (OSCE and NATO) to international monetary policy (IMF). What is more, participation in such organizations appears to reduce the likelihood of violent conflict among member states.

International Nongovernmental Organizations

Much recent scholarship analyzes global structures and processes as distinct level of social reality. The world is more than networks or systems of economic and political interaction and exchange; it has become a single international society, or world polity.

International nongovernmental organizations (INGOs) have proliferated spectacularly, from about 200 active organizations in 1900 to about 800 in 1930, to over 2,000 in 1960, and nearly 4,000 in 1980, but little systematic attention has been given to this domain of global organization. Unlike states, INGOs lack the rational-legal authority to make or enforce law. Unlike global corporations, they have few economic resources.

Since 1850 more than 35,000 private, not-for-profit organizations with an international focus have debuted on the world stage. Associations, societies, foundations, unions, committees, clubs, leagues, conferences, groups, federations, conventions, the range of designations is extraordinary. They include the Pan-American Association of Ophthalmology, the International Exhibitions Bureau, the Commission for the Geological Map of the World, the International Catholic Child Bureau, the International Tin Council, and the Tug of War International Federation. Most are highly specialized, drawing members worldwide from a particular occupation, technical field, branch of knowledge, industry, hobby, or sport, to promote and regulate their respective areas of concern. Only a few such as the Scout movement, the International Olympic Committee, the International Red Cross, and the World Wildlife Fund, are widely known.

Universalism

Humans everywhere are seen as having similar needs and desires. They are capable of acting in accordance with common principles of authority and action, and they share common goals. In short, human nature, agency, and purpose are universal, and this universality underlies the many variations in actual social forms. Most INGOs are quite explicit about this: any interested person can become an active member, and everyone everywhere is a potential beneficiary of INGO activity.

Universalism is evident also in the breath of INGOs' claims about what they do. Physics and pharmacology are presumed to be valid everywhere. Techniques for playing better chess are not country-specific. Red Cross aid will alleviate suffering in Africa as well as in Asia. Across every sector, the purposes and means of action promoted by INGOs are assumed to be useful and meaningful, right around the world.

Most INGOs adopt a purer form of universalism that stresses the fundamental uniformity of all human actors. Scientific, technical, professional, medical, and business-related INGOs rarely allow much room for particularism, and they account for the great majority of all INGOs.

INGOs are embodiments of universalism, individualism, rational volunteeristic authority, progress, and world citizenship. Decentralized world authority among states both facilitates transnational organizing, because centralized barriers to rational voluntarism are weak, and forces transnational organizations to focus their attention on states. In mobilizing around and elaborating world-culture principles, INGOs lobby and harangue states to act on those principles.

The Framework for Inquiry

Decision making in international organizations occurs within a context comprising the functions, the institutional framework and basic procedures, and the historical development of the agency.

Given the nature of the international system, the creation of an international organization requires concrete action by states. Usually, although not always, such actions are consecrated in a treaty. In any case, understanding must be achieved about what is to be done, and how.

International organizations have been set up to perform a variety of tasks: keeping the peace, promoting

economic development, allocating the radio frequency spectrum, reducing obstacles to trade, ensuring that technology is used only for peaceful purposes, and facilitating the maintenance of stable exchange rates to name only a few.

In order to describe how decisions are usually arrived at in a particular international organization, it will be useful to classify the actors involved, to consider the ways in which they may exercise influence, and to list the modes of decision making that may be employed.

The actors in international organizations may be classified according to the following categories: representatives of national governments; representatives of and international private associations; the executive heads of organizations; high officials and other members of the bureaucracy of each organization; individuals who serve in their own capacity formally or informally as advisers; representatives of other international organizations, and employees of the mass media.

Of course, not all of these classes of actors will be active in all organizations. For each category of decisions, however, the actors will fall into one or more of these classes, and it is important to know which of these categories of actors typically have the most influence on the outcome.

Thinking About the Future of the International Organization System

In order to think about the United Nations (UN), we must escape the narrow perspectives of daily press coverage as well as the mainstream of the scholarly agenda. Harlan Cleveland believes that the study and teaching about international relations is usually hung up on what's wrong with the picture: riots and their suppression, military takeovers, drug traffic, corporate raids, financial psychoses, arm races, wars, and rumors of wars. If you stand back and assess the whole scene, you see numerous international systems and arrangements that are working fairly well. Examples include weather forecasting (World Weather Watch [WMO]); eradication of infectious diseases (WHO); international civil aviation (ICAO); allocation of the frequency spectrum (ITU); globalization of information flows; agricultural research for development; UN peacekeeping and peacemaking; ozone treaty; cooperation in outer space; law of the sea; the UN high commissioner for refugees; the Antarctic treaty.

The stage on which the drafters of the UN Charter performed was built during a long historical process, at least 500 years through which human inquisitiveness, restlessness, and acquisitiveness produced ever-increasing contacts among human settlements, across even longer distances. The results of this historical process presented opportunities at San Francisco that had evolved out of growing experience in peaceful cooperation among peoples. But there were also constraints produced by tendencies toward wars of increasing geographic scope with weapons of rapidly increasing destructive power.

If we look back in time from San Francisco, we readily see that the UN is a child of the League of Nations. It incorporates important institutional developments of the League, such as an international secretariat and the growth in importance of economic and social activities during the relatively brief history of the League. The UN Charter also reflects efforts to gain from the League's failures, as in procedures for deployment of military forces by the Security Council in response to aggression.

Nor was the League wholly a product of its founding conference, the Paris Peace Conference of 1919. The century bounded by the Congress of Vienna (1815) and the outbreak of World War I (1914) and became regarded as the era of preparation for international organization. The League evolved out of the Concert of Europe created by the Congress of Vienna, and united to create a new Europe out of the ruins of the Napoleonic Wars.

Humanity was placed on an irreversible path toward the league and the UN even earlier than 1815, as far back as in the late 15th century, when Europeans began a pattern of worldwide exploration that eventually led to extensive empires in Africa, Asia, and Latin America, and to Western domination of the world. Europe-based empires eventually led to the creation of a worldwide system of states. In its early years, the UN was deeply involved in the creation of independent states out of former colonial empires.

In developing a historical perspective it is worth remembering the depiction of the century between 1815 and 1914 as the era of preparation for international organization. How should we characterize the period between the founding of the League of Nations (1920) and today? Very apt would be the era of preparation for global governance. What have the pioneers in this first era of global organizations left as their heritage? They have achieved universality; they

have created a network of global organizations responsive to a growing agenda of global problems; they have established a continuous, worldwide presence of his system of organizations, in at least 134 cities on all continents; they have made multilateral decision making commonplace and have developed new procedures for achieving consensus; they have greatly increased the number of tools available for peace building; they have achieved and made substantial progress in multilateral definition of a set of fundamental global values, such as peace, human rights, development, and ecological balance; they have made progress in breaking down barriers between the people of the world and global governmental organizations.

Overall we can conclude that there is much more potential for moving forward from this era of preparation for global governance than either the daily headlines or the mainstream of international relations research and teaching recognize. Supportive of possible greater employment of this potential are the vitality of INGO and NGO involvement in the UN system, and the large number of creative proposals coming from outside the UN system. Employment of this potential could move more rapidly if governments of states were able to perceive more clearly the long-term interests and needs of their people. This, in turn, might be facilitated by broader media coverage of the UN system, as well as scholarship that offers more probing analysis for the betterment of humankind.

UNIVERSALS IN CULTURES

The universals in culture, which is part of the academic field known as the humanities, cannot be defined in a simple statement. The universals are the cumulative artistic and intellectual achievements of humanity.

They are a body of work created by those who have been singled out for special praise, extraordinary achievers of whom all human beings can be proud. But they are also the universal artistic and intellectual experiences of those who appreciate, and also participate in, the global experience.

The universals in culture are the study of great achievements in art and philosophy and the critical process by which they can best be understood and communicated to others so that they will never be forgotten.

The universals in culture, if understood, could also be a technique for living, accessible to every human being who wants to do more with life. They are a way of life filled with joyous moments of thought and esthetic pleasure.

When one understands the universals in a culture or cultures he or she will be addicted. Song and story, music and dance, and words and ideas, once embraced, become an essential part of life.

This article is intended to reaffirm the value of the humanities as they are represented in the universals of culture. As we are embarking into the new millennium we have to redefine the term human, and we must expand it far beyond anything known to our ancestors. We have a golden chance to enjoy the many dazzling facets of human genius as represented in the universals of culture.

In understanding the universals in culture we must understand the classification of culture. In other words we have to comprehend the classifications of

ourselves, who we are as humans beings. The best person that has done this is the German philosopher, Friedrich Nietzsche (1844–1900), who applied the term *Apollonian* to describe order, logic, clarity, moderation, and control in society and in the human personality, and the term *Dionysian* to describe rebelliousness and reform in society, and spontaneity, passion, and excess within the human personality. Apollo was the god of the sun, hence of light and truth; Dionysus was the god of the earth, of spring and renewal, hence everything that was natural and beyond rational analysis.

Technology

As we analyze the universals in culture, we have to examine technology and humanity. Although the urge to create machinery is probably as old as the urge to create art, technology and humanity have not always been good friends. Instead of being viewed as servants of humanity, aimed at making life easier, machines were often seen as monsters that might take over the world. The global debate is superfluous by now, however, because technology is here to stay, and the issue becomes one of deciding how much technology we truly need and how best to keep technology from running our lives altogether.

The Industrial Revolution of the late 18th and early 19th centuries cleared the way for modern technology, but many writers, and philosophers were wary.

The novels of Charles Dickens (1812–1870) denounced the factory system, the exploitation of the poor, and the cruelties of child labor, which were seen as byproducts of technology.

The German philosopher Karl Marx (1818–1883) responded negatively to the new industrial age, viewing it as an opportunity for the further separation of the haves and have-nots.

To practice the art of being human requires free choice among significant options, and choice exists even in our heavily technological age. Today, opposition may be found in preference for crafts as opposed to factory made goods. There are many who refuse to own cars, but ride bikes or walk instead, many who even ban televisions from their homes. Yet protest does not imply total abstinence. Some people, such as the Amish, seem to get along without electricity, phones, radios, or television, but for the majority, a life devoid of all technology is unthinkable.

Love

We can scarcely overestimate the importance of love to most of us. Even the successive marriages of those disappointed by previous love are evidence that people keep looking for it. From early adolescence on, many seem to believe that, without love, life has been totally wasted or at least has been lacking in an important ingredient. The theme of many poems, novels, plays, operas, and works of visual art is love, as a source of both pleasure and pain. However it is defined in real life or in art, love is not just a matter of romance and marriage. It includes family relationships, friendship on many levels, and even a variety of games. It has been said that love and hate are opposite sides of the same coin, that one cannot hate when the object is not or has not been loved. Perhaps no other area of human experience is subject to so many interpretations and so much misunderstanding, or has been such intense source of anxiety, as has the concept of love.

Body and Soul

Despite the sentiments in poems and songs that love is timeless, despite the frequent use of the words eternity and forevermore, one is better off facing the probability that, if it is to have any meaning as a major force in human life, love has to be considered in relation to specific contexts. We cannot assume that everyone everywhere has been moved by an identical experience or entered into a relationship with identical expectations, no matter how similar the vocabulary. The context of love includes both historical time and geography.

The people in a certain remote area in Africa have no word that translates as "love," though parents probably show what we would consider affection for the young by teaching them how to survive in a hostile environment. In that harsh world, there seems to be little need for close family bonds and certainly none for romance between adults. In the ancient world of Greece and Rome the word love appears in poetry, philosophy, and mythology, but a citizen of that world, alighting from a time machine, would probably not understand if he overheard us saying "Love is blind" or "Love is the answer." Assuredly the time-traveler, having caught the latter sentence, would respond: "What is the question?"

Despite the many definitions and practice, the Western world has been influenced for centuries, up

to the present, by a huge distinction that was made by the Greeks between eros, or love as physical lust, and agape, or love as a spiritual or intellectual relationship. Plato has given us a famous analysis of love, which includes both kinds of experiences.

Myths

Before any discussion of the four-letter word myth is possible, we must first think about other four-letter words: real and true. Contrary to popular usage, myth is not the opposite of those words. Myth is neither unreal nor false; rather, it is a necessary part of human existence, extending back in time, according to mythologist Joseph Campbell, to the Neandertal period (CE 250000–50000 BC).

Mythology developed not because a few people got together to make up stories. It had a deeper purpose than entertainment. Mythology is made up of stories told to each other to explain death and natural disasters, to justify burial and other sacred rituals, to create a sense of identity for a people, and to provide their heroes and their enemies. Myth can include folklore, fairy tales, fantasy, magic, and the supernatural as active forces in human life. It offers spells and curses as ways of accounting for the evils that beset us, but it also gives hope in the form of magic potions, rings, and secret words that the future will be better. The most enduring of all myths, in many versions in many cultures, tells of the eventual arrival of a wonderful someone who will take care of all our problems.

Mythology can provide the underpinning for beliefs about racial superiority and inferiority, and thus renders those beliefs difficult to question. It promises that hard work will bring success. To those who would like to rid the world of myth with the antiseptic broom of science, the mythologists would counter with questions about the myth of science as something that can answer all questions.

Thus, when we talk about mythology, we are dealing not with stories that represent erroneous views of life, but with an entire discipline within the humanities, a discipline that has had a profound influence on human development as has religion, philosophy, or any of the arts. The myth making process reveals much about how humanity has coped and is still coping with the puzzle of being alive.

Nor is a myth confined to ancient history. Even in our enlightened age, people are nervous, frightened, and in need of heroes. Heroes come from the

collective mythology of the human race. So do villains and mysterious strangers who come from out of the fog, and solve our problems before disappearing once more.

There are primarily three categories of myth. The first is myths of childhood, sometimes named fairy tales; these stories, found in many cultures, have similar ingredients, such as witches, demons, elves, and strange, often terrifying landscapes.

A second category of myths is myths as explanation. Many of these arose in what are sometimes called prescientific times, centuries before there was anything like urban civilization. They seem to have fanciful explanations of natural events that had to be understood: storms, volcanic eruptions, eclipses, thunder, lightning, and other natural phenomena against which our ancestors must often have felt helpless. Imagine living at a time when nobody knew why the sun rose and set or what the stars were. Imagine, also, the genius of our ancestors who were not content with ignorance, and so imagined explanations for these phenomena.

The third category, archetypal myths, is regarded as the most important by many scholars who study myths to try to discern what motivated them and what they have in common. These are found the world over. All cultures have invented, told, and passed along stories in which certain characters (such as heroic leaders) and certain recurrent themes (such as magic numbers) have influenced the way people understand their existence,

An archetype is a model by which other characters, events, or ideas resembling it can be identified. The hero is an outstanding example, a person who stands out from the crowd because of very special characteristics. The hero is a universal mythological archetype, indicating to us that people have always needed and continue to need a belief in the amazing powers of a rare few born to lead, whose insights and courage enable them to take on challenges and obstacles that would defeat ordinary mortals.

The psychologist-philosopher Carl Jung (1875–1961) maintained that all persons are born with an instinctive knowledge of certain archetypes, the models by which we comprehend our experience and cope with the enormous and often baffling task of being human.

Death, Attitudes, and Life Affirmation

Just as we might study the humanities in terms of Apollo and Dionysus, asking whether a given work

appeals mainly to the intellect or to the emotions, so might we devote considerable study to the question of whether an artist or philosopher is life affirming or life denying.

Refusing to acknowledge mortality may bring temporary comfort, but as we grow older, the fear of death, if it has been suppressed throughout our lives, can begin to undermine the happiness we might otherwise enjoy. Conversely, the subject of death has motivated some of the most glorious works of visual art, music, drama, and literature. For example, after the death of Brian Epstein, manager of the Beatles, John Lennon is reported to have commented, “Well, he got through it.” Nothing was said about the fact that Epstein was in what we would normally consider the prime of life. His passing was not called untimely by those who knew him well. The diaries of Herman Melville, author of many novels including *Moby Dick*, confide in the reader about the artist’s troubled soul, seldom at home in the world, apparently unaware of his own towering genius, a state of mind he shared with a fellow genius, Vincent van Gogh. Yet Epstein’s apparent negativity, Melville’s struggles with his inner demons, van Gogh’s despair over lack of recognition combined with a constant questioning of the merit of his work, not to mention renowned writer Ernest Hemingway’s depression over what he regarded as a waning of his creative powers, all these artists’ difficulties only served to ignite the fires within them. Melville wrote one of his masterpieces, *Billy Budd*, just before his death; Hemingway penned *The Old Man and the Sea* while he was battling the shadows; van Gogh never stopped painting until despair totally overcame him; and Epstein was able to put his personal troubles aside as he mapped out a brilliant future for his charges.

That the work of many tortured beings lives on and inspires us with joy is often more than enough to affirm the goodness and the wonder of life. Of course, the secret is that greatness sometimes is achieved through agonizing pain and self-doubt. And sometimes the genius behind the greatness never transcends the pain, though we are the beneficiaries.

So looking at the larger perspective of universals in our culture, we can say that the humanities offer us reasons to cheer and reasons to weep. The humanities awaken us to the realities of both pain and triumph. In so doing, they assist us in taking an unflinching look at our own lives, in which we find both life-affirming and life-denying elements.

In life affirmation, the issue is the profound realization that the potential for a productive, exciting life belongs to each of us. We control our attitudes, as Zeno the Stoic would be quick to remind us.

An ancient symbol of life affirmation is that of the phoenix, a mythological bird of rare and exotic plumage and supernatural powers. The Greek historian Herodotus reported, however, that the phoenix actually existed and was known to have Egyptians every 500 years. The Roman belief was that each era bears witness to the birth of one phoenix, that it lives for a very long time, and that at the moment of death, it generates a worm that becomes the phoenix for the next age.

Yet another version of the legend is that the phoenix is a bird from India that lives for 500 years and then flies to a secret temple, where it is burned to ashes upon the altar, only to rise from the ashes 3 days later, young and resplendent.

In folklore, poetry, and song, in fiction, drama, and epic, the phoenix has endured through time as a symbol of rebirth, new growth, regeneration, and redemption. Religions have counterpart symbols: gods who die or descend into the underworld, there to remain for a time and then to rise, reborn and renewed.

Death itself, biological death, the single stroke that happens only once to each of us, will come as it may. One will find in the universals in all cultures sources of life-affirming models, such as the myth of the phoenix, models we have the power and the right to use as we reinvent ourselves and continue to be born anew.

Perhaps the best way to end this discussion is by quoting Joseph Campbell, the mythologist and philosopher, who cried out to us, "Live!"

UNIVERSALS IN LANGUAGE

The term *language universal* refers to those features or properties of language that are common to all languages. The notion that languages might share universal features creates a tension of sorts with conceptions of language, as developed by Boas and other early linguistic anthropologists, that held that languages (along with their respective cultures) were infinitely variable, that there were no constraints on the form a human language could take. This view was seriously challenged, in the second half of the 20th century, by the work of Chomsky and other linguists, and also by work on cultural universals carried out by anthropologists such as Berlin, Kay, and Brown. Universals can be found at all levels of language analysis, including phonology, morphology, syntax, and semantics. However, it is important to note that some universals are more universal than others; universals may be absolute, implicational, or relative.

Features that are found in all languages, without exception, are called absolute universals. For example, all languages: make use of dual patterning (phonemes → morphemes), have a low unrounded vowel similar to [a], have the principle of structure dependency, allow both *yes-no* and *Wh-* questions, allow for negation, have morphemes with the properties of nouns and verbs, and have pronouns for both first and second persons.

Implicational universals take the form of entailment propositions: if *x* is present, then *y* is also present. For example, if a language has a rounded front vowel, such as the [y] of French *tu*, it will also have the corresponding unrounded front vowel, in this case [i] as in *dire*. If a language has, like Japanese, subject-object-verb (SOV) word order, it will probably have post (rather than pre-) positions. If a language has a word denoting the color blue, it will also have words for green and yellow.

Relative universals refer to tendencies, features that most, but not all, languages have. For example, languages tend to have at least five vowels, but some, such as Aymara (Bolivia) have three. Most languages have nasal consonant sounds like [m] and [n], but Wichita (Native American language from western USA) does not. Similarly, languages tend to have pronouns for third person (*she, he, they*), but Latin does not.

All proposed language universals are hypotheses constructed from a sample of what is available; as hypotheses, they are always subject to falsification. For example, while it appears that all known languages had or have a vowel similar to [a], we could, in principle, come across a previously unknown language lacking that vowel. It could also be the case that languages that existed in the past, but that disappeared before any written or other record of them could be made, did not have a vowel similar to [a].

— Ronald Kephart

UNTOUCHABLES

The term *untouchable* is an English translation for the Indian terms *antyaja* and *achhoot* and refers to individuals and groups who inhabit the bottom rung of the hierarchical Indian social order known as the caste system. It is a social status forced upon those who either allegedly made serious transgressions against established orthodox Hindu rules of purity and conduct, or because of the defiling nature of their occupations are considered unclean. During the 20th century, several names have been coined in reference to them, including Harijan Scheduled Castes, and Dalit. The 1991 Indian census estimated the number of Harijans at 16%; however, many believe this number to be as high as 20% or higher.

The caste system has clouded origins in ancient India. Briefly mentioned in the *Rig Veda*, traditionally considered the most revered of ancient Hindu texts, it is a system of four *varnas*, or castes, that divide the society into priests and teachers, warriors and rulers, merchants and farmers, and laborers and servants. By the beginning of the Common Era, a fifth caste had been added, the *anchama*, or *antyaja*, the Untouchable. Members of this caste were placed outside the caste system (*avarna*), because their duties involved cleaning up after all the other castes or undertaking those tasks that were too impure and polluting for others to perform. Occupations in the category include leather workers, sweepers, scavengers, funeral workers, and so forth. The *Manusmriti* (third century BCE–third century CE) elaborates rules and restrictions for the various castes and firmly places Untouchables out of reach of most aspects of Hindu social and religious life that are available to the other castes. This text has continued to be used by the Hindu orthodoxy to justify the system and the inherent discrimination it perpetuates.

Treatment of Untouchables by orthodox and other caste Hindus has varied by time and region, with some *avarna* having had greater opportunities and rights than others. At its best, orthodox Hindu society has treated Untouchables like children, not yet capable of the rights of other adults to take part in the bulk of social and religious traditions. At its worst, Untouchables have been persecuted, tortured, and killed when attempting to step outside the narrow confines that orthodox Hinduism has placed on them. In many village regions, they have been relegated to living on the outskirts, forbidden to enter temples, not allowed in many schools, and prohibited from drawing water from wells used by caste Hindus. In some regions of the country where the percentages of *avarna* Hindus is high, they have been more able to create their own communities, build their own temples, dig their own wells, and, within reason, live like most other Hindus. Nevertheless, the majority of Untouchables are never far away from discrimination that has nothing to do with anything more than the reality of their birth. It is for this reason that attempts to overthrow the practice of untouchability are almost as old as the practice itself.

Terms of Identity

Harijan—In an attempt to remove some of the stigma associated with the commonly used terms for

Untouchables at the time, *avarna* (without caste) and *achhoot* (Untouchable), Mahatma Gandhi began to refer to them with the term Harijan (God's children or God's people) instead. While in prison in 1933, he helped found the Harijan Sevak Sangh, an organization focused entirely on combating untouchability. He also started a new weekly publication, which he titled, *The Harijan*. In it, he regularly described and railed against the practice and the degraded status Harijans faced. As a result of Gandhi, many Untouchables adopted the term for self-identity, and it is arguably the most popular term in India in reference to them today.

Scheduled Caste—The term *Scheduled Caste* first came into use in The Government of India Act, passed by the British in 1935. Among its provisions were several designed to benefit those groups who, at the time, were being referred to as Depressed Classes. The Act changed the classification to Scheduled Castes. From that time, it became the official terminology for *avarna* Hindu groups, and it continues to be so, for the most part.

Dalit, a term literally meaning depressed or down-trodden, was first used in the 1800s by an Untouchable social reformer named Jyotirao Phule, in reference to the social and religious situation in which Untouchables were forced to live. He adopted the term as a badge of honor. However, it was when another Untouchable, Namdeo Dhasal, started the Dalit Panther Movement (named after the U.S. Black Panther Movement) in 1972, and thereby gave the name real currency and a wider use. Like its namesake, the organization had a strong militant overtone to its stated goals and rhetoric. By the mid-1980s, it split into a variety of factions.

Since that time, the term *Dalit* is used primarily by social and political activists, most of whom are either Marxist, secular, or converts to a non-Hindu religion, especially Islam, Christianity, and Buddhism. While many Dalit activists claim the movement speaks for all Harijans, this is not the case, especially regarding Harijans who still consider themselves Hindu. In reality, very few rural Harijans have much of an awareness of the Dalit movement, which is primarily a phenomenon of urban and western India. Nevertheless, Dalit writers and activists have done an immense job of shedding light on the oppressed situation of Harijans, and this has led to an increase of pressure on the Indian Government, both from within India as well as internationally, to address more forcefully the

problem and work to eradicate the discrimination. The influence of the movement is such that even the Indian Government has recently begun to adopt the term in reference to Harijans.

The Struggle Against Untouchability

Throughout much of recorded Indian history, orthodox rules of behavior have justified discrimination against those at the bottom, the *avarna*. At the same time, criticism of the practice also dates back to ancient times as well. In some of the earliest Buddhist writings, the Buddha rejects a system that bases one's worth on birth rather than actions. Since then, most religious reform movements that have arisen in India, especially devotional movements, have rejected birth-based social and religious status determination. Moreover, this has been one of the central themes in many of the movements. Yet, these attempts at reform had only limited, regional, or temporary success, and the practice continued. Finally, thanks primarily to the efforts of two 20th-century figures in India, Mahatma Gandhi and Bhimrao Ramji Ambedkar, Indian attitudes toward Untouchables gradually began to change.

Mahatma Gandhi (1869–1948)

Mahatma Gandhi was an important figure in attempting to rid the Indian social system of untouchability. Some say he was as concerned with its removal as he was with the removal of British control over India, and he frequently spoke and wrote against the practice. However, Gandhi did not reject the caste system per se. This is because he had seen poverty and oppression of the poor in England as well, so he did not believe the British social system to be as superior to India's. His love of India's cultural and religious traditions led him to feel that the caste system should remain but be cleansed of untouchability. As a consequence many Untouchables and anti-caste activists disliked him and refused to work with him in his efforts toward the eradication of untouchability. Among the more notable of these figures was Bhimrao Ramji Ambedkar.

Bhimrao Ramji Ambedkar (1891–1956)

Bhimrao Ramji Ambedkar was the most powerful and well-known Untouchable activist and leader in the first half of the 20th century, and he was among the principal authors of the Indian Constitution. He

came from an educated and relatively well-to-do family in India and did much of his higher education in the West, including in America, England, and Germany, earning both a doctorate and a law degree. The primary focus of his life's work and activism was the eradication of untouchability. In the process, he inspired the wrath and ire of both the British government and many caste Hindus. While his goal for the eradication of untouchability was similar to that of Gandhi, the two remained distant in their approaches. Not only did they not work together, often they worked at odds with each other. The main point of contention was between Gandhi's belief that the caste system could be cleansed of untouchability and Ambedkar's reject of the system in its entirety.

Several years after Indian Independence and his drafting of the Constitution, Ambedkar removed himself from politics. He had increasingly come to believe that Untouchables would never be treated equally as Hindus, so he turned his focus to Buddhism. In 1935, Ambedkar had sworn that he would not die a Hindu, and true to his word, in 1956, he formally converted to Buddhism. Immediately thereafter, he led the conversion of nearly 400,000 Harijans who were present as well. Seven weeks later he died, and in his honor nearly 750,000 more Harijans converted to Buddhism. Since that time, his inspiration has led to several million more Buddhist converts. Consequently, Ambedkar Buddhists are the most populace denomination of Buddhists in India today.

Fighting Untouchability in Contemporary India

Pro-Hindu Activists. While orthodox religious organizations and institutions continue, for the most part, to adhere to traditional attitudes toward avarna Hindus, forbidding or sharply restricting their participation in religious activities, other Hindu organizations are increasingly opening their doors to membership for all Hindus, and some have made concerted efforts to include Harijans. This is especially true of those organizations that have an international following and tend to be influenced by Western values. Even the Vishwa Hindu Parishad, an international but largely conservative Hindu organization, has come out against untouchability and has vowed to work toward its demise. Additionally, there are various religious organizations and movements started by Harijans themselves in an effort to work toward social equality,

and also to create an environment in which they can freely express their own forms of religious and spiritual beliefs and practices.

Dalit Activists. As mentioned earlier, those who identify themselves as Dalit have, for the most part, rejected participation in the Hindu tradition, choosing either to convert to another religion or to follow a Marxist ideological approach rejecting religion altogether. Their influence is primarily urban, where untouchability is lessening for a variety of other reasons as well. However, Dalits are having relatively little effect in most of rural India. Nevertheless, they have been successful in influencing elements of the Indian Government, and Dalit activism may have inspired some of the more recent government policies to help Harijans.

Those Dalits who have converted to Christianity, Islam, or Buddhism, however, face an additional dilemma. After conversion, they often continued to be viewed as Untouchable by members of their new religious communities as well, and thus continue to face the same discrimination as when they were Hindu. Yet, now they are no longer qualified to participate in the benefits of the multiple government programs, which provide assistance in education, housing, vocational training, government employment, and even in securing elected positions. This is because on conversion, they are no longer officially members of the Scheduled Castes, which is a Hindu category. While the government is clearly being pressured to continue looking upon the converts as Schedule Caste members, this would be a de facto acknowledgment of the existence of untouchability in these religious traditions as well, and because many of their leaders officially deny its existence in their religions, several have been firmly against the move.

Nonreligious International Organization. A variety of international organizations have turned their focus on untouchability in India as a human rights issue. They have sought to confront the Indian government and its representatives on the issue in various forums. As an example, at the World Congress Against Racism and Xenophobia, held in South Africa in 2001, Indian government supporters fought hard to keep out any discussion of caste discrimination and untouchability, which they depicted as an internal issue for India. Nevertheless, a large number of Dalit activists attended the conference, and the issue was hotly debated with

the objective of having untouchability officially recognized by the United Nations as a form of racial discrimination.

Indian Government. Ever since Indian Independence in 1947, the Indian Government has been attempting to address the problem. The Indian Constitution of 1949 outlawed the practice of untouchability and any discrimination based on race, caste, sex, or place of birth. It also contains 14 separate Articles that deal with the issues of discrimination and create special provisions for members of castes considered backward. The Indian Government continues to work on the issue. It has shown that it understands the negative effect the persistent discrimination has on the economic progress of the country as well as how it is viewed on the international stage. Almost every year, new laws or amendments to existing laws are enacted to address the problems.

Along with this, various organizations and activists continue to exert tremendous efforts to facilitate Harijans' equal participation in caste Hindu social and religious life. Nevertheless, the prejudice and discrimination continues, and change has been slow to come, especially in rural areas. The persistence is primarily out of both indoctrination by, and fear of, the religious orthodoxy. Anyone who crosses the caste line in eating and close physical relations runs the risk of being ostracized by his or her community. This situation is maintained by the orthodoxy's continuous depiction and treatment of Harijans as polluted individuals, and its refusal to allow them into the mainstream of religious life. As a consequence, untouchability continues to affect where people can live and work, what they can and cannot do, and with whom they can interact socially, including eating, playing, and marrying. Thus, while government and activists work for changes, the reluctance of the orthodox hierarchy to address the issue more forcibly continues to benefit anti-Hindu activists in gaining international support and a reason for rural Harijans to convert to other religious traditions.

Lack of education, economic power, and political representation remain the major factors that keep Harijans at the bottom of the social, economic, and political ladders. This is especially true in the rural areas of the country, and it is in these areas where discrimination remains the most prevalent. However, as more and more schools are being built, and an increasing number of Harijan children are becoming

educated, changes are occurring, albeit slowly. In urban India, however, life moves at a more rapid pace. Less and less is caste an issue. In some states, it is illegal to ask caste affiliation, and one can rarely know by looking at an individual. Economic class is replacing caste as the primary determinant of one's status. Because education and job training in the cities is more available to them, an increasing number of urban Harijans are availing themselves of these opportunities, resulting in better paying jobs, an increased awareness of their legal rights, and the knowledge of how to demand them. In the process, many urban Harijans are learning to navigate their lives away from the constant shadow of discrimination. Their rural counterparts still have a long way to go.

Located in modern southern Iraq, the ancient site of Ur (Arabic: Tall el-Muqayyar) grew from a modest agricultural village to one of the most important cities of Mesopotamian civilization. Popularly known as the birthplace of Abraham, the Biblical patriarch (Genesis 11:28–31), Ur remained an important

Source: FreeStockPhotos.com.

economic and religious center from the fifth millennium to the first millennium BCE.

Although several archaeologists had worked there briefly before him, the excavations of British archaeologist C. Leonard Woolley, between 1922 and 1934, produced the bulk of our knowledge on ancient Ur. Woolley's deep soundings revealed that a 25-acre city was founded during the Ubaid period (fifth millennium BCE), one of the earliest periods of Mesopotamian urbanism. Following the Ubaid settlement, Woolley encountered a sterile deposit of water-born sediments he believed was evidence for the Biblical flood story in Genesis 6:9; today, scholars agree that the Euphrates river deposited these sediments during periods of seasonal flooding.

Starting in the fourth millennium, during the Uruk and Jemdet Nasr periods, a cultic precinct was established that would remain in use throughout Ur's history. The earliest temple was set on an artificial platform and decorated with colored cones set into the mudbrick walls. Burials associated with the prehistoric periods were excavated both in formal cemeteries and under house floors.

Beginning in the Early Dynastic period (2900–2350 BCE), Ur became one of several city-states in ancient Sumer whose history is preserved in excavated cuneiform tablets. A new temple was built above the previous temple with plano-convex bricks,

a hallmark of early Dynastic building styles. Adjacent to the temple precinct, Woolley excavated what he described as the Royal Cemetery, a necropolis where approximately 2,000 graves were interred between 2600 and 2100 BCE. Lady Puabi was buried in a vaulted chamber within a well-preserved tomb (800), wearing extravagant jewelry of gold and lapis lazuli. Puabi was interred with attendants—musicians, guards, and servants—who apparently drank poison moments before the tomb's closing. Such instances of mass graves are rare in Mesopotamia, but speak to the power and wealth of Ur's royal family.

Starting in 2100 BCE, Ur became the capital of a unified Mesopotamian state. During what is known as the century-long Ur III period, the city's kings added to the preexisting temple precinct, erecting a temple dedicated to Nanna, the moon god and patron of the city, atop an enormous ziggurat. Cuneiform tablets dating to the Ur III period attest to the city's elaborate bureaucratic practices and its extensive trade relations with societies on either side of the Persian Gulf.

The Ur III period ended when the neighboring Elamites destroyed Ur in 2000 BCE; the city never regained the status it held during the preceding millennium. The city remained occupied despite its decline in importance, and Babylonian and

Assyrian kings renovated Ur's temple precinct from time to time. The city was finally abandoned around 400 BCE.

URANIUM-LEAD DATING

The Uranium-Lead (U-Pb) Dating is a method that encompasses several techniques that are employed in determining the geological age of both terrestrial and extraterrestrial (for example, meteorites) rocks. The method was first suggested by Boltwood in 1907 when he postulated lead to be the decay product of uranium. The method has a dating range from 4.55×10^9 years ago to approximately 5×10^4 years ago, and takes advantage of the long decay chains of the radioactive parent atoms such as ^{238}U , which spontaneously decays through 13 transitional stages until it reaches ^{206}Pb , which is stable and is termed the daughter.

^{238}U has a half-life of 4.47×10^9 years; the transitional stages have an accumulated decay time of 0.0073% of the primary half-life permitting the parent-daughter comparison for chronometric purposes if a closed system with accompanying equilibrium conditions exists. More recently, Uranium-Lead Dating methods based on closed system disequilibrium conditions have been developed (Figure 1).

Lead contains a mixture of four isotopes: ^{204}Pb , which is primordial and stable, and three radiogenic isotopes ^{208}Pb , ^{207}Pb , and ^{206}Pb , which are the end-product daughters of ^{232}Th , ^{235}U , and ^{238}U (^{232}Th : $t = 1.41 \times 10^{10}$ yrs; ^{235}U : $t = 7.038 \times 10^8$ yrs; ^{238}U : $t = 4.47 \times 10^9$ yrs). Therefore, the ratio ($^{208}, ^{207}, ^{206}\text{Pb}/^{204}\text{Pb}$) of the respective daughters (9.56, 10.42, 28), to the original ^{204}Pb will decrease with time in a measurable manner termed a “growth curve” that can provide what is called a “model age” using the ratios. The ratio change with time can be seen in the diagram of $^{207}\text{Pb}/^{204}\text{Pb}$ vs. $^{206}\text{Pb}/^{204}\text{Pb}$ (Figure 2).

Furthermore, there are three diagrams that can be generated from rock data that provide ages from the

Figure 1 shows both the radioactive parent-stable daughter relationship between ^{238}U and ^{206}Pb , and some radioactive parent-radioactive daughter relationships. The latter relationships provide dating potential for closed systems in disequilibrium, while the former provide dating potential in closed systems in equilibrium.

Figure 2 shows the important role that ratios of lead isotopes play in dating minerals. Growth curves can be determined independently of the uranium content. $V = {}^{235}\text{U}/{}^{204}\text{Pb}$.

straight lines produced by plotting ${}^{206}\text{Pb}/{}^{204}\text{Pb}$ vs. ${}^{238}\text{U}/{}^{204}\text{Pb}$, ${}^{207}\text{Pb}/{}^{204}\text{Pb}$ vs. ${}^{235}\text{U}/{}^{204}\text{Pb}$, and ${}^{208}\text{Pb}/{}^{204}\text{Pb}$ vs. ${}^{232}\text{Th}/{}^{204}\text{Pb}$. Therefore, an independent number of independent estimates of the rock's age can be obtained by measuring the lead isotopes and their parent isotopes. If the results agree, it is likely the age obtained is a fair approximation of the actual age. If the results conflict—a common problem because uranium and lead may be gained or lost from many minerals—the problem of loss or gain of isotopes is readily apparent. Using plots such as that shown in Figure 2 (lead-lead technique), the effects of lead loss can be minimized because it determines the ages from the lead isotopes alone. This approach permits a researcher to chart at what points in time metamorphic heating events may have occurred, thus helping to unravel the geological history of a rock or mineral.

With the development of more sophisticated analytical techniques in recent decades for directly measuring parent and daughters and their α , β and γ decay products, attempts have been made to quantify in a meaningful way the intermediate decay products of ${}^{232}\text{Th}$, ${}^{235}\text{U}$, and ${}^{238}\text{U}$. These decay products are compared both with the parents and among themselves producing a wide range of techniques that span a period of days to greater than a million years (${}^{234}\text{U}/{}^{238}\text{U}$: 50×10^3 – 1.5×10^6 yrs; ${}^{227}\text{Th}/{}^{235}\text{U}$: 10 – 200×10^3 yrs; ${}^{224}\text{Ra}/{}^{228}\text{Ra}$: 2 – 20 yrs, ${}^{210}\text{Bi}/{}^{210}\text{Pb}$: hours –50 days).

They are based on the disequilibrium of a daughter decay product rather than the equilibrium required for dating using the parent and stable daughter. These methods require that either a parent or a daughter be chemically separated by natural processes and remain thereafter in a closed system. The age limits obtainable are based on the half-life of the daughter or daughters, and the age upon the measured degree of return to equilibrium conditions. Unlike the rock and mineral limitation of traditional Uranium–Lead Dating, the disequilibrium method can be used on a

wide variety of materials, including minerals in young volcanic rocks, bones, egg shell, wood, mollusks, terrestrial carbonates, and marine and lacustrine sediments.

URBAN ECOLOGY

Urban ecology is the study of humans and non-human organisms in urban areas, their interaction with their surroundings, and their reactions to environmental change. Anthropologists use theories, principles, or methods developed by ecologists to study how past cities arose, how current cities develop and change, and the effects of urban environments on people.

Ecological Theories of Urbanization

Archaeologists often use ecological theory to explain how relationships between humans and their environment have evolved, leading to urbanization. These theories are based on Thomas Malthus' proposition that human population always tends to increase unless checked by some force. The British archaeologist V. Gordon Childe argued that the birth of agriculture led to surplus food and sedentism (people remaining in a fixed area). This allowed more people to specialize in crafts, arts, or political functions, and socioeconomic differences among people are more pronounced in ancient cities than in rural archaeological sites. In the 1950s, cultural evolutionists such as Leslie White used systems theory to argue that all cultures tend to become urban as they increase the energy they capture and use. Karl Wittfogel, Julian Steward, Marshall Sahlins, and Robert Carneiro portrayed urbanization as unique ecological adaptations to particular environments, such as the need for political organization to regulate agricultural irrigation in arid areas. Ecological explanations remain important, but currently are usually integrated with warfare, ideology, and individual agency as explanations for the emergence of cities.

Ecological concepts are also used to explain how contemporary cities grow and change. In the 1920s urban sociologists Robert E. Park and Ernest Burgess founded the "Chicago School" of theory by encouraging students to study cities as laboratories. They used ecological concepts to explain urban growth and change, proposing that cities are comprised of ecological niches arranged in concentric rings around a central core. These sociologists considered the city an ecosystem requiring energy to maintain segmented niches, which experienced residential succession much like patches of forest. Individual human expectations and aspirations depended on an inhabitant's location within these niches. The Chicago School's later focus on demographics and statistical analysis of census information was criticized for lack of attention to individuality. Their quantitative techniques continue to dominate urban planning and research.

Environmental Impacts and Sustainability

Cities produce pollution and their expansion reduces habitat for native species. Researchers are also interested in how these effects feed back to change cities.

For example, rain in coastal cities washes nitrogen from lawns and city streets into rivers, and eventually the estuary, where it can change the structure of shellfish communities. This can negatively impact shell-fishing economies and threaten a region's sustainability. Archaeologists such as Charles L. Redman and Joseph Tainter argue that environmental deterioration often led to abandonment of urban areas in the past. In 1992 the Canadian ecologist William Rees introduced the concept of "ecological footprint" to describe the far-reaching environmental impacts of cities. Urban planners and activists interested in sustainable development attempt to quantify ecological footprints. It is also important to understand what people in cities "value." The nascent field of ecological economics is an attempt to integrate concepts like ecological footprints with market-based analyses for decision making. Social ecologists such as Steven Kellert argue that concern about wildlife conservation is higher among urban residents, which suggests a positive environmental effect of urbanization.

Anthropologists George J. Armelagos and Mark N. Cohen, the historian Lewis Mumford, and biologist Jared Diamond have written about past tendencies for human health to deteriorate with urbanization because risk of disease increases and nutrition declines. Currently, urban pollution creates asthma epidemics, and mosquito-borne illnesses persist in many cities where the natural hydrology has been altered, among other problems. "Diseases of affluence" are also on the rise. A 2004 report by the RAND Corporation linked urban sprawl and reliance on automobiles to increased risk of asthma, high blood pressure, heart disease, and diabetes. Sustainability research is an attempt to identify why disadvantages begin to outweigh the benefits of urban life, and to correct problems through planning or social activism. Social scientists collaborate with geographers and ecologists using geographic information systems (computer mapping) that combine satellite imagery and aerial photography with census or questionnaire data to identify relationships between environmental quality and social conditions. When integrated with computer models of a city's production of nitrogen, use of water, or energy budgets, such approaches can be used to analyze a city's sustainability.

Urban Ecology and Social Movements

Low-income and minority populations are more likely to live in parts of cities identified by ecologists,

toxicologists, and epidemiologists as unhealthy. “Environmental justice” refers to social activism and academic research focusing on this relationship. Environmental sociologists such as Dorceta Taylor, and anthropologists like Melissa Checker and Vivienne Bennett, argue that environmental injustice is often related to discrimination based on gender, race, or class. In the late 1800s, the landscape architect Frederick Law Olmstead advocated using nature in parks to break down barriers between social classes in American cities, an approach still advocated by urban social ecologists such as William R. Burch. Some restoration ecologists (who typically restore habitats for wildlife) are attempting to restore human relationships with natural processes in urban areas; for example, integrating resources like water-purifying wetlands or urban forests with community-based development (a process in which neighborhoods plan, finance, or otherwise implement their own development projects).

Future Directions

The United Nations estimates that the global population living in cities will exceed 50% for the first time in 2007 and continue to rise. Biologists are beginning to study biodiversity *in* urban areas, and how social forces shape landscapes. Archaeological debates about the extent to which ancient cities were more or less healthful than their hinterlands, and what ideological or organizational shifts lead to urban sustainability versus collapse, will gain relevance. Applied anthropologists are being challenged to integrate their knowledge of social dynamics with ecological data to promote sustainable social change. Technological advances in computer mapping will allow for more collaboration between ecologists, toxicologists and social scientists studying urban environmental justice and sustainability.

URBAN LEGENDS

Urban legends are those fanciful tales that grip listeners and are spread widely across continents and oceans while repeated by individuals often claiming the facts reported in the tale happened to a “friend of a friend,” or are based on “facts” reported in news reports that the teller of the tale had allegedly read in the past. A classic example of an enduring urban legend is the enduring tale of the blind, white alligators that inhabit the sewers of New York. In the legends, sun-seeking tourist return from Florida with pet alligators, small babies that quickly became unmanageable and their owners, unwilling to kill them, simply flush them down the toilet. In this environment rich in food (rats), but lacking in sunlight, the alligators became blind albinos, witnessed by the occasional unwary New Yorker of urban legend.

Although urban legends are seen as modern manifestations, in terms of structure and role, they are not necessarily urban nor are they legends in the strict sense of the term. What they are is popular folklore that seeks to transmit popular lore—the knowledge or wisdom of the people—that are spread from individual to individual usually through narrative retelling of the tales. Academic interest in urban legends began in the first half of the 20th century as folklorists shifted their interests from the rural folk to cities where the majority of Americans and Canadians lived after World War I. Two scholars can be credited for coining and propagating the term urban legend. The first is Richard Mercer Dorson, who is credited with having coined the term, and who was already, in his 1959 book, *American Folklore*, writing about the legends in the big city and the legends of college students (active propagators and audience for urban legends). The other is one of Dorson’s students, Jan Harold Brunvand, who popularized contemporary research on urban legends with a series

of publications examining American urban legends, beginning in 1981 with *The Vanishing Hitchhiker: American Urban Legends and their Meanings*.

Unlike traditional legends, urban legends are reported as contemporary events: the narrative power is derived from the narrative performance of the urban legend in which the audience—a friend, a group of colleagues on break, or fellow students in a dorm—are recounted a story that “actually” happened. Although urban legends spread thousands of kilometers, even over the ocean from England to North America or from North America to Australia, urban legends are invariably localized and contemporized: though the underlying story remains unchanged, the facts are changed to make it fit into the locality and the time period.

Although an urban legend may have a grain of truth, the origins of the legend—if it can be found—is often far removed from the tale that the listener will hear and has often been changed considerably as local details will be added to localize the legend. A case in point is “The Philanderer’s Porsche” an urban legend that was recounted as “fact” in an Ann Landers’ syndicated column that was published worldwide in 1979. In the letter Landers published, a man in California is said to have seen an ad in the paper for an “almost new” Porsche for the measly price of \$50. Although skeptical, he nevertheless visits the woman selling the Porsche, and when he discovers that it is a legitimate car and sale, he buys the Porsche. However, curious, he returns to the woman who explains that her husband had run off with his secretary and instructed her (the wife), to sell the Porsche and send him the money. The author of the letter claimed to have read the ad in his local newspaper (the *Chicago Tribune*); in turn, Ann Landers’ managing editor thought that he had read the story. Upon subsequent fact checking, the story was shown to never have existed, though both the person who sent the letter and the newspaper’s editor sincerely believed they had read the account in the news.

The managing editor of the *Chicago Tribune* did not need to feel too guilty, as newspapers are often published as “fact” in newspapers around the world. This particular legend, of a philandering husband and his wife selling his car, was in circulation in Great Britain since at least 1948, and published as “fact” on several occasions. Likewise, newspapers across North America will publish accounts of razor blades allegedly inserted in apples given out to children who are out

trick-or-treating on Halloween night even though there exist no verified cases of sabotaged apples.

The examples of urban legends cited above fall into the popular motifs of the urban legend. Many of the tales can be described as cautionary tales, articulating some of the fears and anxieties of society. One such tale is the “old woman” and her new microwave. Gifted a new microwave by her children, the woman decides to use it to dry off her dog. Returning a few minutes later, she discovers that her dog had been cooked from the inside out. The legend highlights the danger of technology: new technology, though useful, may conceal hidden dangers.

One characteristic of a successful urban legend is the unexpected twist at the end of the narrative: it is outlandish, but seemingly plausible, and thus is taken as truth. It often mixes humor and horror, appealing to an individual’s sense of morality or hidden anxieties to touch a chord of empathy. In the case of the Porsche, the listener will empathize with the wife and feel a certain sense of satisfaction that the unfaithful husband got what was coming to him.

Although urban legends are primarily oral narratives, they can be transmitted using a variety of means. As noted, urban legends often appear in newspapers reported as “true” events. They are also integrated into popular culture in television and movies. In 1998 the movie *Urban Legend* appeared poking fun at the genre, and was followed in 2000 with the sequel *Urban Legends: Final Cut*. Nonetheless, urban legends live on, and e-mail and the Internet has given urban legends new life. Although urban legends have always demonstrated the remarkable ability to travel far and wide, with instantaneous communication of e-mail, new forms of urban legend are emerging.

One example of a recent urban legend that was circulated widely was the report that authorities were planning on imposing a surcharge on e-mail. This urban legend seems to have originated in Canada, but quickly spread to the United States where it was modified to suit local tastes: in 1999 instead of requesting recipients of the e-mail message to write their Member of Parliament (Canada), American recipients were directed to write their representatives and say no to Bill 602P. This e-mail in circulation was thought to be true, even though it had no basis in fact, as neither Canada nor the United States ever had any pending legislation to impose a surcharge on e-mail messages. By the year 2001, the e-mail was in circulation in Australia and the citizens of this state

were being warned that their federal government was planning on imposing a 5-cent surcharge on all e-mail messages.

New urban legends continually emerge, and the Internet is serving as a medium to record this new folklore. However as mediums of communication change along with North American society, folklore will invariably live on, enthralling new generations.

URBANISM IN ANCIENT EGYPT

Although ancient Egypt was once described as a “civilization without cities,” contrary archaeological evidence has mounted as increasing numbers of settlement sites have been surveyed and excavated. Settlement archaeology began taking off in Egyptology in the 1970s, and was manifested particularly in the innovative research projects at El-Amarna, Elephantine, and Hierakonpolis, amongst other sites. These programs were partly designed to answer the question of what we know about ancient Egyptian cities, towns, and villages apart from their architectural details.

Ancient cities were unique in deriving a substantial portion of their income from their rural hinterland. As such, a broad-based model can take as its basis that a city is a unit of hierarchical settlement performing specialized tasks with an interactive hinterland network.

Developmental differences in urbanization, as expressed through evolving nature and functions, are the underlying premise of Wilson’s claim that ancient Egypt did not possess cities until the New Kingdom. Wilson’s biological metaphor assumes what Kemp has termed “an intuitive appreciation of culture in which archaeology has little place,” and narrowly defines the concept of urbanism on the basis of Mesopotamian size and style.

Wilson’s evaluation does not differ fundamentally from the rationale presented for the development of Egyptian settlements by Helck in his *Handbuch der Orientalistik*. Both models are based on varying Egyptian religious texts from different periods and an interpretative approach that excludes towns due to the “spiritual” foundations of Egyptian society.

The problem with using the religious Pyramid and Coffin texts to inform on the nature and degree of urbanism, per Wilson and Helck, is that the ancient Egyptian designations for their own settlements tends to be overlooked. There was no distinction made in the Old Kingdom between towns and other settlement forms.

A different model has been proposed by Hassan, who postulates that the ideological and social context of agriculture and trade differed from the mercantile economies of the preindustrial Middle Ages in Europe. Thus, these activities may be reflected in a territorial state spatial organization, with settlements hierarchical in character tending toward activity boundaries being defined, and the activities themselves becoming the domain of specialists. Thus activities would be focal in nature, designed to take advantage of the scaled settlement patterns relating the city to its hinterland, and to minimize the fluctuations in agricultural yield, caused by the unpredictability of the Nile flood levels, through food transportation networks.

Hassan’s definition of “capital cities,” referring to national capitals (for example, Memphis and Thebes), “town” to nome capitals, and “village” to rural settlements, is applicable to later dynastic Egypt. However, his model fails to demonstrate their appropriateness for both late Predynastic (Nagada I–III) and Early Dynastic Egypt. Hassan discretely broaches this problem when stating that a structure of 22 nomes was fixed by Fifth Dynasty times; however, nome boundaries were mobile. Because his model for the spacing of settlements is dependent upon population estimates generalized over the time span of dynastic

Egypt, and a hierarchical structure of administrative and redistributive sizes for settlements, its inherent inflexibility renders it problematic for the developing nucleated city-states of the predynastic, and the evolving manifestations of the territorial Pharaonic State.

Bietak defines four additional characteristics for distinguishing between settlement types: (1) Artificially-planned towns such as Amarna, Piramesse, and probably Early Dynastic Memphis; (2) Gezira-towns, which predominate in the Delta (e.g., Buto and Tell Ibrahim Awad); (3) Levee-towns, built on the top of high levee-banks; and (4) Tell-towns. A comprehensive inventory of 217 cities, towns and fortresses was compiled from Egyptian textual sources and analyzed by Butzer. His category, “city,” refers to Luxor-Karnak and Memphis, the two national metropolises. The small and large centers were defined as market redistributive nodes for agricultural, economic (crafts, harbors), residential, and religious (cult centers with connected wide-ranging temple estates) activities.

Despite the large-scale, monumental architecture dating from the Middle Kingdom onward, no *in situ* Early Dynastic or Old Kingdom remains have been located. While possibly later occupational activity and/or sebak-diggers may be responsible for this discrepancy, it has been argued that early Memphis was a mobile capital located close to the pyramid complex being constructed by the particular pharaoh at the time in the Memphite necropolis, Lower Egyptian Memphite nome. Love bases her hypothesis on scattered remains from Giza, Abu Rowash, Abusir, Saqqara, and Dahshur as well as on linguistics. The Greek-derived name Memphis stems from *Mn-nfr* meaning “Pepi is firm[ly established] and well.” Thus Lehner has referred to the necropolis as a “capital zone,” a nonnucleated 30 km stretch.

Assmann described New Kingdom Egypt as “the exact imitation of cosmic government on earth.” O’Connor has applied this concept to royal cities such as el-Amarna and Thebes, suggesting that these cities were laid out to replicate and function as the cosmos. The temples were the reciprocators of the cosmic power, channeled to the citizens through the palaces, and thus maintaining the relationship between the city and the cosmos, and the pharaoh and his people.

In this hypothesis, Amun-Re at Thebes was the cosmic ruler of a cosmic and secular entity. The administrative palace and the temple were linked, but O’Connor pushes the limits of his hypothesis by

postulating “the residential palace, like Amun-Re’s horizon, was perhaps remote from the city proper.” His hypothesis is more solid for al-Amarna where the residential palace is located at the northern edge of the settlement, mirroring the sun-Disc’s emergence at the cosmos’ edge, the eastern horizon (*akhet*). The pharaoh and the Disc join in sacred union in the city centre, before the pharaoh continues on to govern in the “secular city.”

O’Connor combines Egyptian texts with archaeological data to further inform the available evidence on the Egyptian’s worldview about the interrelationships between city, state, and the cosmos through examining not only temples but also the internal layout of palaces and towns.

O’Connor fails to adequately develop his cosmological hypothesis to account for population numbers and spatial interrelationships between cities, towns, and villages, and for the spacing of the settlements in the landscape. Hassan’s functionalist model fails to adequately account for the ecological variability of the Nile floodplain. The fundamental principle of versatility and state ideology sometimes superseding functional constraints is clearly evident when viewed from peripheral sites such as Elephantine.

Instead, it is most plausible to conclude that ancient Egypt was a territorial state with a plurality of hierarchical settlements distributed across its landscape, constrained and reinforced by considerations of ecology and mobility, as well as logistical and ideological considerations.

UXMAL

Located in Mexico's modern-day state of Yucatán, Uxmal was a Late and Terminal Classic Maya center with considerable political and economic clout. The name Uxmal is thought to derive from Yucatec Maya, and roughly translates as “thrice built.” Given its history and spectacular architecture, Uxmal is well named.

Archaeological excavations at Uxmal have been minimal, but consolidation of structures in the urban core has shed light upon the center's later history. Little is known about the earliest occupation of Uxmal, ca. 600–300 BC. However, the last major building episodes—and the ones that are presently

visible on the surface—date to the ninth century, and indicate that the center reached its apogee during this time. With the demise of Maya centers in the southern and central lowlands, sites in the northern lowlands, such as Uxmal, flourished during the Late and Terminal Classic periods (ca. AD 600–1000). Evidence of increased building activities and expansion of trade networks testify that Uxmal was an important urban center. By AD 1000, the city was abandoned for reasons that are poorly understood, but may be connected to Chichén Itzá to the east and the rise of the Itzá, a Maya group who wielded considerable influence in the Postclassic Maya world. Nonetheless, religious pilgrims periodically visited Uxmal over the next three centuries.

Uxmal is best known for its distinctive Puuc-Chenes architectural style. Puuc style buildings are visible on the surface today, and date to the late and terminal classic periods. Chenes style buildings, entombed within Puuc architecture, represent earlier construction phases. Chenes buildings are low-lying and rectangular in shape; they are commonly found at Maya sites throughout the central lowlands of northern Guatemala (the Peten), and southern lowland sites near the Usumacinta River, which forms the

Guatemala–Mexico border. Named for the low range of hills that crosses the northern Yucatán, the Puuc style of architecture has several distinguishing features. Stone masonry was fine cut with no mortar. Sculpture and mosaics were concentrated on structures' upper façades. Buildings were vaulted, and had corbelled doorways and roofcombs. Certain structures were oriented with respect to astronomical and solar events. Notable and visually stunning buildings at the site include the House of the Governor, Nunnery Quadrangle, and House of the Magician. In particular, the House of the Governor is an impressive low-lying "palace" situated on an artificial platform. The building served as an elite residence and administrative center. Intricate masonry work depicts the rain god Chac, serpents, netted motifs, and astronomical symbols. It is likely that the structure was built to commemorate Lord Chac, one of the last reigning rulers. The seated human sculpture that hangs above the central doorway may in fact represent the ruler.

In his wanderings throughout Central America, 19th-century explorer John Lloyd Stephens offered a detailed description of the center's "magnificent" and "lofty" edifices. In 1996, UNESCO inscribed Uxmal as a World Heritage Site, as its ceremonial structures "represent the pinnacle of late Mayan art and architecture in design, layout, and ornamentation." A visual and political force to be reckoned with in its heyday, Uxmal today remains a prominent and striking marker of national identity.

VALUES AND ANTHROPOLOGY

Anthropology has the highest regard for rigorous and honest research. Most anthropologists respect the internal, culturally defined explanations of truth of the people they study (*emic*) while doing scientific research (*edict*). Both types of research are part of cultural anthropology. In both cases, social facts are determined by observation; this requires actual field research. Both types of anthropology follow similar types of observation: by carefully recording the native *worldview*, attempts to understand another culture are undertaken. The anthropologist's carefully constructed analysis of any aspect of a culture studied is taken from an objective point of view, and must be pursued with equal qualified fairness and honesty. Anthropologists have a professional commitment to record what has, in fact, been observed, and those conclusions must honestly reflect what they claim to be studying through their observations. It is also important that other anthropologists could, if not replicate those studies, at least use the studies as valuable background for further research.

As in all social sciences, there is a code of conduct in Anthropology on how to do research. Anthropologists generate hypotheses that are to be internally consistent so that they do not create incongruous conclusions. The social scientist has an obligation to others in the profession as to their talent to make available truthful, however tentatively, calculations of what was observed in the field. These truthful observations are always helpful to other anthropologists, and making sure of the availability of these observations is seen as being a true professional. Even research in areas carried out in studies that are not only geographically distant, but that also have a certain theoretical distance as well

from the original hypothesis, is appreciated by other anthropologists. In cultural anthropology, as a branch of learning in which use of the scientific methods are sometimes less than clear-cut, a good hypothesis can be even more important. As in the early days of anthropological explorations, the hypothesis should be able to combine contrasting observations recorded in the field notes of the anthropologists. This rigorous recording is still seen as a virtue within the profession. Also sympathetically appreciated among anthropologists is the use of simplicity of research design and sophistication of theory. The truly learned among this field show a strong appreciation for elegance in the study; like any science, honesty within the research and its resultant findings is first and foremost.

Today most anthropologists believe they have an obligation to the people they study. A social scientist with conflicting allegiances cannot always be relied upon to act in the public interest of those people being studied. In the field of anthropology today, it is acknowledged that enticements often exist that may tempt the field researchers to betray the trust of the people they are studying. To do this, it is important to remove as many conflicting interests as possible, including the often conflicting interests between the loyalties to those who pay the anthropologist, the loyalty to the discipline of anthropology, and the loyalty to the people anthropologists study.

This must be the first concern of professional anthropologists: to respect the integrity, anonymity, and the culture of the people they study. These concerns take priority over all other considerations. A close secondary issue is the need to be concerned with the contribution to the overall body of knowledge of culture, and the development of anthropological theory.

Finally, in the ethical value system of the social scientist, there is an applied legal responsibility to the

organization funding the research. The anthropologist must be concerned with what possible uses will come out of the research, and how this may affect the people being studied. Policy issues are always a concern before the anthropologist ventures out into the field. Who decides the fate of the people being studied is a major concern to be taken into account.

Two primary issues that are of concern for anthropologists are *cultural relativism* and *value-free* research. Cultural relativism is the thesis that all cultures are unique and, therefore, can be evaluated only in accordance with their own principles, values, standards, and morals. *Ethnocentrism* is the belief that one's own culture is superior to others. For an anthropologist, to be ethnocentric is deadly. The use of cultural relativism prevents the anthropologist's ethnocentrism from corrupting the results of any anthropological research.

Herskovits states that the use of cultural relativism does not mean that one can abdicate moral responsibility for the injustice within the dominant society toward tribal and peasant populations. Herskovits takes the position that to use cultural relativism in a self-serving way to further one's career is unethical. This means that the term cannot be used in objective anthropological research in order for the dominant culture to gain access to the resources of tribal people. The concept of cultural relativism was originally an answer to Western ethnocentrism. Western ethnocentrism has done more harm to many cultures than any other type of ethnocentrism. The forced *assimilation* of American Indians in North America through the boarding school system of the late 1800s and early 1900s is only one example of this.

Culture determines the shared values of any people. All cultures are ethnocentric, but science helps researchers to suspend their moral judgments while studying other people.

Ethics are not scientific; ethics look at how things should be. The anthropologist develops a set of professional ethics, those of tolerance and nonintervention. Western values, taken as absolute, have justified policies that have seriously harmed other peoples. This is why Herskovits promotes a type of scientific research in which anthropologists can suspend their own culturally defined values and observe other cultures in a more sympathetic way. The researcher learns not only how things are done, but also the local values of why they are done that way. Herskovits pointed out that cultural relativism is not *ethical*

relativism, but *pluralism*. Most criticisms of cultural relativism have come from outside of anthropology; critics often claim that, following cultural relativism to its logical conclusion, one would have to support Nazi and Fascist extremes. Herskovits points out that Nazi and Fascist extremes were part of European ethnocentrism.

The idea of value-free research is that the researcher must remain detached from what is being observed. Objectivity is a primary virtue in any research. The values and prejudices of the social scientist must be suspended while carrying out the research. The social scientist must use measurements and data that any researcher can easily duplicate with the same results, meaning that what is being measured is what the researcher is actually studying. Thus, personal values need to be put to one side so as not to corrupt one's results.

It is understandable that such notions lead to passionate disputes, and are very contentious in anthropology. *Rational discourse* is another name for value-free. Central to this perspective is the idea that there exists an objective world that is independent of the observer. This world can be known through careful observation. Through rational empirical observation, and through using the scientific method, a commonly shared body of knowledge is expanded. All social scientists should share this set of information. Truth does exist independently of interpretations. Social science must remain free and neutral of political interests and cultural biases. Social reality must first be observed without moral interpretation to gain an understanding of the social world. Categories must not only be quantifiable but also mutually exclusive, with a strong preference for mathematical exactitude. Tools that are used in social science are those of objective measurements, standardized particulars, quantifiable information, and controlled statistics.

Rational discourse devotees claim that only by understanding the determined nature of what researchers are studying can they hope to make rational choices about the world in which they choose to live. Societies and nature follow lawful processes, operating beyond our control. *Determinism* operates behind our backs because we do not understand these lawful processes. Whatever choices we make have long-term consequences. To control these lawful processes we must first understand them objectively.

Not all anthropologists agree with the concept of value-free social science; the research values of rational

discourse have been attacked on many levels. Many anthropologists assert that it is hypocritical to maintain any claim of objectivity. The topic chosen for doing research, the theoretical models used, and even types of studies, all reflect the preconceived notions of the social scientist. Statistical analysts begin with assumptions about which data is relevant. Other conjectures about how to categorize the data are always highly subjective. Subjective choices are made about which statistical techniques to use and how to interpret the results, and thus subjectivity is unavoidable.

There exist heated political debates about why anthropology is even studied. Always, it is claimed, all research reflects not only individual biases but individual political agendas as well. The researchers must admit to their agenda because, as anthropologists, they study people. Another question often asked is if it is even ethical to attempt objectivity. It is claimed that politics is central to all science. Science evolved along with the evolution of a market economy. Science has served capitalism well by creating this worldview of objectivity in which truth is independent of ethics. The Industrial Revolution and the continuing revolution in technology could never have happened without embracing this worldview.

The all-encompassing reliance of scientific research on private or government funding has created a give-and-take pecuniary support. This type of dependence creates its own definition of professionalism. Because most studies are carried out either within a university setting or through research institutions, bureaucratic control becomes necessary for continued funding. Anthropology, being more exotic than, say, chemistry, is generally less rigidly controlled by administrators. This is a major reason why the very ethics of science has been called into question by anthropologists. It has been argued by a growing group of dissident anthropologists, or *critical anthropologists*, that all science, social or otherwise, has a political agenda. Practically speaking, this debate leads to three types of applied anthropology: the realists, the critical anthropologists, and the purely intellectual anthropologists.

A small group of *realists* (those who are often seen as “mainstream” applied anthropologists) work cooperatively with neoconservative groups to attack issues of sovereignty and social benefits going to the poor. Critical anthropologists (*radicals*) see themselves as advocates to empower the powerless, at least until these powerless groups become powerful enough to be their own advocates. Those advocates of intellectual

autonomy (*intellectual anthropologists*), value-free science, and objectivity, criticize both realists and radicals.

Critical anthropologists claim science helps legitimate existing power relations, by accepting funding to do research. The university remains dependent upon this funding, and thus seriously limits any possible impartiality or academic freedom. Peer review keeps the dissident in line.

The critical anthropologists further challenge the discipline by claiming that anthropologists, like all professionals, have their own class interests to maintain. Critical anthropologists claim that the majority of anthropologists seek to develop a professional worldview, language, culture, and body of knowledge; they use these to market their own individual power within the profession and with those who control promotion, tenure, and research opportunities and funding.

This view claims that anthropologists exploit the people they study in order to develop professionally. Autonomy is maintained because the type of research being done supports the capitalists and government agencies; it is said that Anthropologists are like all scientists in this regard. The “ivory tower” syndrome is possible because collaboration with the non-science elite is brokered by the university administration and granting bodies. The discursive fads and unethical practices of social science are highly centralized. As in all science polemics, the aggressive attacks on each other are embedded within the essential consensus on professional ethics.

Internal politics within individual anthropology departments, and serious competition with sociology departments, have all too often linked individual anthropologists to government and business interests. Tenure, promotion, professional rivalry, and peer review often reflect these influences. Competition for professional recognition often influences choices of research topics.

Competition for funding has a direct influence on the direction in which the discipline itself goes. These competitive wars also artificially separate academic departments. All of the above tends to restrict individual anthropologists, limiting the success of any innovative practices. Funding provides a check on innovation while maintaining “epistemological orthodoxy.” This conformist commonsense approach maintains artificial boundaries by defining legitimate research.

Anthropologists have long had to deal with the fact that what they do has a real impact on the people they

study, and that their responsibility does not stop with publishing their articles. The traditional view of anthropologists is one of “realism.” The global spread of an industrial market economy cannot be stopped. Development needs to be regulated to lessen the injury and distress of modernizations on traditional rural communities. Science can be used to integrate people into a global market economy while helping those impacted people adjust to the disruptions to their lives. Anthropology as advocacy has grown increasingly popular since the late 1960s. Many anthropologists have increasingly come to believe their first responsibility is not to the discipline of anthropology, but to the people they study. Some anthropologists will state that people have a right not to be integrated into the global economy, to have their own history on their own lands, and to make their own mistakes. More and more, anthropologists are forming joint advocacy groups with the leaders of the groups of people they study, going beyond cultural relativism to social activism, using academic credentials to defend less powerful people against “colonialism,” not as leaders, but as advocates. Groups such as Cultural Survival Inc. have formed to help endangered groups struggle for cultural and political sovereignty. Self-determination and indigenous control over their own lands, resources, and communities are replacing protection of impacted groups as a major theme in applied anthropology. Though there are still many anthropologists who work with government and private development plans, there is now at least an open debate on the moral responsibility of anthropologists.

A small group of anthropologists openly embrace the title “romantic.” They feel that indigenous people have a lot more to teach than to learn from industrial nations. Western society is seen as inferior in its ability to adapt to the natural environment while providing for the material needs of all its citizens. Marshal Sahlins calls tribal society the “original affluent society.”

There has now developed from these new groups of dissident anthropologists a set of ethics, used as a check on potentially unethical anthropology. To begin with, there needs to be a way to create a standard for a way of thinking, for choices of research topics and methodologies that will do no harm to the people studied. Freedom for the pursuit of truth as social scientists means the second concern is to protect anthropologists from their employers in government, university administration, or private funding agencies from influencing the results of their studies.

The political end of any research remains an important consideration. Self-restraint in research is a must at all times, to prevent the establishment of bureaucratic watchdog agencies that may not understand the issues involved.

Funding is a particularly difficult ethical problem. The researchers must ask to what purpose the results of their research will be used. If the potential for harm is instigated by the funding agency, then the research should be terminated.

In conclusion, the values of the anthropologist reflect three separate issues. First there is a professional commitment to carry out the best possible research. Anthropologists must use the highest professional standards in carrying out that research, if they are to be accepted as professionals. Second, anthropologists of all theoretical schools must accept responsibility toward the people they study. Third, anthropologists need to understand the legal contract carried with the employer or funding agency. Beyond that there is little agreement. Even the degree to which anthropology is a social science is highly debated. Issues such as the desirability of objectivity or value-free observation has come under attack since the late 1960s. The controversy is a long way from being settled. This brings up the closely related issue of cultural relativism and to what degree the anthropologist’s responsibility is to the people being studied. Increasingly, a larger number of anthropologists come to strongly identify with people other than those in centers of power. If the anthropologists closely identify with people seen as oppressed, exploited, and powerless, this puts them in conflict with the funding agencies, which pay for research. There is little agreement as to what the role of anthropologists will be in the future.

VAYDA, ANDREW (1931–)

Andrew P. Vayda is retired from Rutgers University, New Brunswick, New Jersey, where he was Professor in the Department of Human Ecology, Cook College, and Rutgers University. Vayda received his PhD in Anthropology from Columbia University.

Vayda has maintained an interest in Popperian methodology and social science. He has taught numerous courses on the role of explanation and methodology in social and ecological science reflecting this interest in the work of Karl Popper. Additionally, his research in Indonesia as well as in other areas has reflected the importance of the work of Popper as Vayda has applied it to his own work on the processes and mechanisms of social and ecological change.

Vayda has been a major figure in anthropological research on human ecology. He has been concerned with the impact of human activity on the environment as well as in developing methods and explanations to explain the environmental effects of human action. Furthermore, Vayda has studied and written on the misuse as well as the proper use of ecological, evolutionary, and sociocultural theory. His interests extend to land use, especially tropical forestland use, conservation, and resource management. More generally he is concerned with the use of practical knowledge, including how it is produced, transmitted, and changed.

He has worked with and taught many of the major figures in the human and cultural ecology movement, including his most prominent student, Roy Rappaport, and the influential Julian Steward. Vayda continues to write influential books and articles, directing attention to the interrelationship between human and the environment while seeking ways to improve that interrelationship.

VENEZUELA

Located on the north coast of South America, Venezuela is a country of stunning scenery and extreme cultural diversity, including the forest-dwelling Yanomamo and modern Caracas with its economy fueled by petroleum. The climate is generally tropical, but diverse habitats from Amazon rain forest to tall, cold mountains support high biological diversity, including at least 21,000 species of higher plants and 323 mammals. With more than 40 living languages, Venezuela provides the stage for some of the most contentious debates in anthropology. Collaborative international research efforts have included Venezuelan, French, German, American, and other anthropologists.

Venezuela includes an area of 912,050 square kilometers—roughly the size of Texas and Oklahoma or France and Italy combined. The total population is 25 million, with an annual growth rate of 1.4%. Most people (85%) live in cities in the north, with more than four million in Caracas, the capital city. The

literacy rate is high (91%). Venezuelans are relatively healthy, having a 73-year life expectancy at birth. Infant mortality is 26 per 1,000 live births. With a US \$3490 gross national income per capita in 2003, Venezuela is one of the wealthier Latin American countries, although 58% of income is concentrated among the wealthiest 20% of the population.

Sustained European contact began in 1499 when the Spaniard Alonso de Ojeda explored Venezuela's Caribbean coast. Caracas was established as a Spanish colonial center in 1567. The indigenous population was exploited for labor throughout the colonial era, and slaves were brought from Africa beginning in 1528. Simón Bolívar was born in Venezuela in 1783, and became the political and military leader of the regional struggle for independence from Spain. Venezuela declared independence in 1811, but the Spanish were not defeated until 1829. Bolívar abolished all slavery by decree in 1812. He is idolized by Venezuelans, and his visage appears in nearly every public area.

The German naturalist Alexander von Humboldt and French botanist Aimé Bonpland studied nature and culture as they traveled throughout the Americas between 1799 and 1804. They collected the first botanical specimen of the rubber tree in Venezuela's Orinoco Basin. The rubber boom that began in Venezuela's southeastern tropical forests in the 1870s led to exploitation and territorial invasion of Ye'kuana, Yanomamo, and other indigenous groups by rubber barons. Prior to the 1920s, coffee cultivated in the coastal foothills remained the primary export product, and led to the early assimilation of indigenous populations. Foreign-owned companies began to develop Venezuela's vast oil resources in the 1920s. A founding member of OPEC (Organization of Petroleum Exporting Countries), Venezuela nationalized its oil industry in 1975, resulting in rapid economic development but limited diversification. The petroleum industry currently accounts for one third of Venezuela's gross domestic product. Approximately 90% of Venezuela's crude oil exports go to the United States. This economic relationship produces a pronounced American influence on Venezuelan politics and culture, including entertainment and consumer commodities. Venezuelans take pride in a democratic two-party system that has existed since 1958. Steadily declining oil prices over the past 30 years have compromised the economy and political stability. Impacts of oil development on indigenous populations have

been severe. Anthropologists Filadelfo Morales and Karl H. Schwerin have described a 40-year struggle between the oil industry and the Cariña people.

Cultural Groups

There are three general cultural groups. Spanish-speaking descendents of colonial immigrants and more recent immigrants from Europe and other Latin American countries work in petroleum, manufacturing, commercial agriculture, mining, and service industries. They are predominantly Catholic. European languages like German and Italian are sometimes spoken within this group.

Roughly 2% of Venezuela's people are indigenous descendents of those who migrated to the area before the Spanish. Most practice either pure or syncretic forms of Catholicism or Protestantism. Venezuela straddles the geographic ranges of the Carib, Arawak, Savila, and Chibcha linguistic families. Languages not assigned to a family (isolates) include Puinave, Hoti, Guahibo, and possibly Pumé. Some of these people were originally foragers who did not plant gardens, but most practiced swidden (slash and burn) horticulture to grow manioc, maize (corn), bananas, and plantains as staple foods—supplemented by fishing, hunting, and collecting wild plants. Some groups like the Yanomamo continue this lifestyle. Other groups like the Barí and Makushi combine subsistence horticulture with commercial agriculture and wage labor. Groups like the Cariña and Paraujano are more integrated into the dominant economy, live in towns, speak Spanish as well as their own language, and occasionally marry outside their ethnic group.

Regarding the third group, Venezuelan ethnohistorian Berta E. Pérez describes the Aripaño of Bolívar State as an example of descendents of slaves who overcame diverse African heritages and banded together in resistance to colonial slavery. Other Afro-Venezuelan groups are concentrated in the state of Miranda. Most speak a creolized Spanish.

The population is unevenly distributed throughout five physiographic zones (Figure 1). The Andes and smaller forested mountain chains in the north separate the dry coast from the interior. Most people live in cities in the coastal plain or lower mountains. Sociologist Audrey James Schwartz's 1975 study of barrios (impromptu neighborhoods) that sprawl up hillsides around Caracas challenged Oscar Lewis's "culture of poverty" theory. Other groundbreaking

urban ethnographies from the area include Lisa Redfield Peattie's analyses of barrios in Ciudad Guayana and Margalit Berlin's participant observation of factory seamstresses. Indigenous groups still exist in this area. Lawrence Craig Watson and Maria Barbara Watson-Franke have studied cultural change among rural Guajiro, including migration to barrios in Maracaibo City. In 1981, Antonio J. López Epieyú published a dictionary of Guajiro language, still spoken by more than 300,000 people. Kenneth B. Ruddle has described change in agricultural strategies among the neighboring Yupka. On the basis of nearly 40 years of research, Venezuelan anthropologist Roberto Lizarralde has described change among the Barí. Further east, Johannes Wilbert, María Matilde Suárez, and Basilio Mario de Barral have published ethnographic and linguistic accounts of the Warao of the Orinoco Delta.

South of the Andes Mountains, the llanos (plains) extend eastward and comprise one third of Venezuela's territory. Extreme seasonal variation in rainfall creates savannah punctuated by scrub woodlands and gallery forests along rivers. Commercial agriculture includes cattle and rice. Large rivers have supported trade networks. Ted L. Gragson's research shows how Pumé along the Apure River rely heavily on fishing to supplement swidden horticulture. Anthony Leeds has explained Pumé social organization using their cosmology. The Guahibo and Cuiva of this area were subsistence foragers, only recently transitioning to horticulture. The Cuiva have endured territorial invasion and genocide by ranchers.

In the east, the Guiana Highlands transition from savannah in the north to mountainous tropical forest in the south. The Pemón and Panare inhabit the transitional zone, where conflicts with mining and commercial agriculture continue. Most rivers flow into the Orinoco River, and are the lifeblood for groups

Venezuelan cultural groups discussed in anthropological literature and major geographical features.

like the Panare, the ethnographic subjects of Jean-Paul Dumont and Paul Henley. Mariano Gutiérrez Salazar's analysis of Pemón cosmology also documents the cultural importance of the area's rivers and mountains. The southern tropical forests of the Guiana Highlands are home to the Piaroa, studied by Joanna O. Kaplan, Pedro J. Krislogo, and Stanford Zent. Venezuelan anthropologist Nelly Arvelo-Jiménez and French anthropologist Marc de Civrieux have conducted ethnographic studies of the Ye'kuana (Makiritare). Walter Coppens has documented invasions of Ye'kuana territory. The Yanomamo inhabit the southeastern forests bordering Brazil. The Wakuénai are found to the less mountainous southwest, where Venezuela's rivers flow to the Amazon.

Issues in Venezuelan Anthropology

Anthropologists have influenced Venezuelan politics through social critique and activism. European colonists and their descendants relied primarily on Catholic missions to acculturate indigenous populations. Napoleon Chagnon and others argued that missionaries negatively affected indigenous peoples.

Filadelfo Morales and Nelly Arvelo-Jiménez have criticized the government's peasant and indigenous development policies since the 1960s as culturally and socially destructive. In 1989 indigenous peoples formed the Venezuelan National Indian Council (Consejo Nacional Indio de Venezuela). They achieved a political victory when many of their rights were codified in the revised national constitution in 1999.

The Venezuelan Institute for Scientific Research (Instituto Venezolano de Investigaciones Científicas) was established in 1952. Jacqueline Clarac de Briceno suggests this shifted Venezuelan anthropology from particularism to functionalism. Much of the new research was ecological. Stimulating one of the most important debates in anthropology, Chagnon used sociobiology to argue that the culturally isolated Yanomamo he studied exemplified a natural human tendency toward warfare, contradicting Rousseau's proposition that "primitive" people are more peaceful. Timothy Asch's films of Yanomamo violence are still widely used in anthropology classes. French Yanomamo ethnographer Jacques Lizot rejects the focus on violence. Marvin Harris's proposal that Yanomamö warfare resulted from environmental protein scarcity stimulated extensive ecological research in Venezuela and elsewhere. Detailed analyses of Yanomamo nutrition and subsistence strategies by Lizot and Raymond B. Hames indicated no protein scarcity.

Paleoarchaeological research suggests that hunting populations had migrated into Venezuela by 11,000 years before present. The exact date of manioc (cassava) domestication is difficult to determine, but appears to have become a staple food by 4,000–3,000 years before present. Maize was domesticated in Mexico, and its cultivation spread eastward into South America. By analyzing carbon isotopes, Anna Roosevelt and her colleagues documented a shift from manioc to maize during the first millennium AD on the Orinoco floodplain. Many Venezuelan populations never fully adopted maize. The archaeological record indicates that beginning around 500 AD, a network of chiefdoms began to emerge in Venezuela, characterized by mound building, extensive trade networks, agricultural intensification, and irrigation. Excavations by Charles Spencer, Elsa Redmond, and Rafael A. Gassón in the western Llanos revealed variable house sizes, burials, and ceremonial plazas that indicate social stratification and centralized authority. Such chiefdoms still existed when the

Spanish arrived. Complex, hierarchical, bureaucratic state structures like the Inca and Classic Maya never developed in Venezuela. Ethnographic research by Anthony Leeds and David John Thomas suggests that flexible subsistence reduces the potential for centralized authority.

Past anthropologists generally considered Venezuelan cultural evolution to proceed from complex pre-Columbian societies to simpler forms after European influence. Neil L. Whitehead, Jonathan D. Hill, Gassón, and others argue that the situation is more complex, with new forms of social organization emerging as indigenous populations cooperated with, or resisted, colonialism. Debates about regional networks of power and trade systems continue, including how important they were, how they changed with European influence, and whether they will continue.

Archaeological and ethnohistorical data show more social complexity emerged in western Venezuela than the east before the Spanish arrived. In the early 1970s, Betty Meggers suggested that chiefdoms did not develop in Amazonia because of poor soils, and thus nature constrains culture. Roosevelt's archaeological research in Venezuela and other Amazon areas, combined with ethnographic evidence from Emilio Moran, Jonathan Hill, Leslie Sponsel, and others, show flexibility in resource use can overcome many environmental limitations. A recent combination of archaeological and satellite data shows that past human activities created much of what was previously thought to be pristine Amazonian forest. Ecological studies from other areas of Venezuela include Stephen Beckerman's analysis of Bari foraging, horticulture, kinship, and protein budgets, and Michael Jeffrey Paolisso's research on Yupka time allocation.

The focus of anthropology in Venezuela, including ecological approaches, continues to shift from tribal to peasant and urban populations and issues of migration. The relevance of ethnohistorical analyses is increasing as people struggle to verify their ethnic ancestry. The biological and cultural effects of acculturation and migration represent an important current area of research. Further integration of ecological, biological, and cultural approaches will influence issues of health intervention and cultural survival, especially among formerly isolated groups like the Yanomamo.

VENUS OF WILLENDORF

The Venus of Willendorf, a small female figurine with exaggerated sexual characteristics, is arguably the most famous example of Paleolithic portable art. It was found in 1908 by archaeologist Joseph Szombathy near the town of Willendorf, Austria, in loess deposits dated to the Aurignacian period (24000–22000 years BP). It is currently housed in the Naturhistorisches Museum in Vienna.

Prehistoric art is generally categorized as either *parietal* cave/wall art, or *portable* art. Portable art consists of small, transportable objects made from stone, bone, antler, ivory, or shell. These objects could be obviously functional, such as spearthrowers, or without an obvious function, suggesting ceremonial or ritual use. Portable objects were decorated with images of animals, humans, or symbols; some were sculpted into animal and human figurines. The human figurines, found throughout Eurasia from Western Europe to Siberia, are almost exclusively female. These female statuettes are generally called “Venus figurines” because they depict a faceless, voluptuous, often corpulent, female body with a heavy emphasis on the breasts, stomach, buttocks, and pubic region.

The Venus of Willendorf is 11 cm (4.3 in) tall, carved from limestone, and fits easily into the palm of the hand. The figurine depicts a fleshy woman with heavy hips and voluminous belly and breasts. Her large hips and thighs taper to small ankles. Her arms are small and are resting above her breasts, and both her wrists are adorned with bracelets. Her head is tilted forward; no face has been carved. However,

much attention was given to her elaborate plaited hairstyle that extends down to the nape of her neck. The plaits are wrapped in seven concentric bands around her head. Originally the figurine was painted with red ochre. The statuette is made of nonlocal limestone, meaning that either the raw material or the finished product was brought to (or traded into) the site.

What do the Venus of Willendorf, and other Venus figurines, represent? With all art, the social context in which these figurines were carved holds the key to what made them meaningful to their owners. The social context, however, is not well understood for these nomadic Paleolithic societies, and there are many interpretations of the role of the Venus figurine.

The most commonly cited interpretation of these figurines is that of fertility fetish or fertility goddess.

Source: © Kathleen Cohen.

To support this view, researchers point to the artist's emphasis on the stomach, breasts, buttocks, and pubic area, suggesting sex and procreation. Some argue that the red ochre pigment originally covering the statue symbolizes menstrual blood, thought to be a life-giving material.

A second interpretation of the Venus figurines is as a talisman. Its small size makes it possible for men to carry it during hunting trips. Its fertility symbolism, again, could be thought to help increase the number of animals, bringing hunting success. Some cite the facelessness of the figurine, suggesting it functioned more as a symbol rather than a representation of a person. However, others argue that to humans, the face is a key feature in identity; since the Venus figurines lack a face, they lack identity, and can be regarded as anonymous sexual objects.

For many researchers, the figurines' fertility symbolism itself is questioned. Whereas some of the figurines appear pregnant, many are simply obese. For these active, nomadic Paleolithic hunting and gathering groups, obesity would be a rarity. None of the few male figurines or images from this period is depicted as obese. If this is an obese woman, she would perhaps have had a special status in the group. From this and the fact that these figurines are widespread geographically, some argue that the Venus figurines serve as an illustration of a prominent female deity identified as a mother goddess. Some researchers suggest that this reflects the relative importance, perhaps even dominance, of women in Paleolithic societies. Alternatively, its function might be tied exclusively to the female sphere, carved by women for women.

Despite the preponderance of explanations, the meaning of the Venus figurines remains elusive, and interpretations often reflect current society as much as that of its makers.

VERNADSKY, VLADIMIR IVANOVICH (1863–1945)

Vladimir Ivanovich Vernadsky, an outstanding Russian mineralogist, biogeochemist, historian of science, philosopher, and political figure especially concerned himself with the origin and historical development of humankind as a natural stage of the biosphere evolution, and a place of man as an “autotrophic” species in a present-day biosphere. The peak of his research work fell on in the period of great upheavals in the history of Russia. Nevertheless, his scientific career, successfully started in the Russian empire, was brilliantly continued in the USSR (Union of Soviet Socialist Republics). Holding high positions, Vernadsky expressed his dissent not once, but—however strange it might be—he was not subjected to repression. On the contrary, he became one of the figures of an official myth about the “coryphaei of natural science” who had come to believe in historical rightfulness of the communist ideas after a long period of hesitation. In the “pantheon of Russian science,” he was given a place of an encyclopedist of the 20th century, a thinker and a scholar who had anticipated future tendencies of science and human development.

Vernadsky was a member of the Paris Academy of Sciences (1922), Czechoslovak Academy of Sciences (1928), Yugoslavian Academy of Sciences, and more than thirty 30 Russian and foreign scientific associations. All elements of an official cult were also present: an Academy collection of his works; numerous republications of writings; books devoted to his work, congresses, conferences, and seminars; perpetuation of his memory in the names of institutes, avenues and streets, metro stations, name grants, and prizes; monuments, memorial plates, and jubilee medals, and the list goes on. Harsh critics of his biogeochemical

works for idealism and vitalism in the 1930s to 1950s changed into violent apologetics in the 1960s. A true renaissance of Vernadsky's scientific work began. Since then, thousands of works have been written about his theory of the biosphere and the noosphere, philosophy, and history of science. Many people have been looking in his books for the answers to the burning questions arising at the present stage of human development. Many of his books have been numerous republished not only in Russia, but in West Europe and in the United States.

The Beginnings of Scientism and Liberalism

Vladimir Vernadsky was born on March 12, 1863, in St. Petersburg in a house in the Millionnaya Street, which starts from the Winter Palace, the main residence of the Russian emperors. His father, Ivan Vladimirovich, professor of political economy and statistics, was a chairman of the Political-Economical Committee of the Free Economical Society (Vol'noye ekonomicheskoye obshchestvo), the publisher and the editor of the magazines "*Ekonomicheskii ukazatel*" and "*Economist*," to which prominent Russian economists, liberal statesmen, and political men contributed. Natural science was popular in the Russian society of the 1860s and 1870s. It was seen as the means of liberation from religion and authoritative power. It's no wonder that, from a very young age, Vernadsky's favorite books were *The Space* by A. Humboldt and *On the Origin of Species* by Charles Darwin. He carried out meteorological observation, took research tours to the outskirts of St. Petersburg, collected herbariums and butterflies, participated in the publication of a hand-made natural scientific magazine in the gymnasium, and regularly read *The Nature* magazine. Young Vernadsky was also interested in historical books, ethical-religious writings, philosophy, philology, economics, and foreign languages; he was fond of fiction, painting, and theater. At a mature age, he could read and write in 15 languages, including Greek, Latin, and all Slavonic, Romantic, and Germanic languages. Evolution of nature, development of humankind, constitutional-democratic reforms in Russia, enlightenment of people, the role of science in modernization of the country, and the Slavonic problem all interested him since his childhood.

From 1881 to 1885, Vernadsky was a student at the Natural Scientific Department of the Physical-Mathematical Faculty of St. Petersburg University, where the flower leaders of in the Russian science gave lectures. Vernadsky took his broad scientific approach from them. The views of the intelligentsia of the postreformed Russia, who called for radical but gradual reorganization of the society, became the source of his becoming a scientist. The views were formed under the influence of the authority of science, which was growing all over the world, amazing discoveries and their technical realization testifying to the near coming of industrial society. Not only scientists themselves, but also a substantial number of manufacturers and politicians all over the world considered science the major factor in the improvement of society. It was becoming clear that the development of science was possible under a powerful state support. Vernadsky believed that it was especially important in Russia, where all scientific creative work was connected—directly or indirectly—with the state.

During a students' meeting in St. Petersburg University on November 10, 1882, and following short-term arrest, Vernadsky got acquainted with some humanitarians, and together they created a circle of liberal orientation. Later on, many of its members became prominent scientists and politicians. Among them was S. F. Oldenburg, who was a permanent secretary of the Academy of Sciences for more than a quarter of a century, and, in fact, was its head during the period of the revolutionary shake-ups. Vernadsky was elected one of the leaders of the scientific-literary society, where Aleksandr I. Ul'yanov—an elder brother of Vladimir Lenin, the would-be head of the Soviet government—was the secretary. In 1886, Vernadsky was elected chairman of an illegal students central council of united *Zemlyachestva* (associations of people of the same area). Its meetings often took place in his house. Ul'yanov and other future participants of the murderous assault on Emperor Aleksandr III were also present there. In 1887, Vernadsky's wife, Natalia E. Staritskaya, a daughter of Senator Egor. P. Staritsky, gave birth to son Georgiy V. Vernadsky, a would-be historian, professor of Yale, Harvard, Columbia, and Chicago Universities in the USA.

The Formation of the Scientist

Vernadsky's teacher was Vasily V. Dokuchaev, the founder of genetic soil science, professor of

St. Petersburg University. Vernadsky carried out his first research in his expeditions in 1882 and 1884. In 1885, he graduated from the university and was offered the opportunity to stay there and prepare for the status of professor. His career, so successfully started, nearly broke down in 1887, when People's Enlightenment Minister Ivan D. Delyanov suggested Vernadsky should turn in his resignation, being accused of illegal activities and contacts with terrorists. Thanks to the interference of Dokuchaev and Staritsky, the resignation was substituted by a research trip abroad. In 1888–1890, Vernadsky was writing his master's theses in the best laboratories of Italy, Germany, France, and Great Britain. He took part in the World Industrial Exhibition in Paris, where he was in charge of demonstrating soil collections of Dokuchaev and his followers. As a result, the Department of Russian Soils got the golden medal at the exhibition.

From 1890 to 1898, Vernadsky was an assistant professor at Moscow University. He completed a master's thesis, "On a Sillimanite Group and the Role of Alumina in Silicate" (1891), and a doctoral dissertation, "The Phenomenon of Crystalline Material Sliding" (1897). He turned the uncoordinated gatherings of the Mineralogical Laboratory of the Moscow University into a valuable museum collection, and the laboratory itself into a research institute. In his first works, Vernadsky already tried to integrate different fields of knowledge (geology, paleontology, evolution) and create important natural scientific and world outlook view conceptions. This attracted youth to him and allowed him to quickly create a powerful scientific school, which united future members of AS USSR geochemist Aleksandr P. Vinogradov, crystallographer Aleksei V. Shubnikov, mineralogist Aleksandr E. Fersman, radiochemist Vitaly G. Khlopin, chemist-mineralogist Konstantin A. Nenadkevich, and others.

Vernadsky went on numerous geological-mineralogical and soil-studying excursions in Russia and Europe and studied geological, paleontological, mineralogical, and meteorite collections in the first-rate museums of the world. The number of his Russian and foreign contacts grew intensively and, by the end of his life, it included more than 2,000 people. In 1888 and 1897, Vernadsky worked out a concept of silicate structure, put forward a theory of kaolin nucleus, made a classification of siliceous compounds more accurate, created genetic mineralogy, and determined

a connection between the form of crystallization of a mineral, its chemistry, genesis, and formation conditions. He paid special attention to practical usage of minerals. In 1903, his monograph "The Basics of Crystallography" came out, and in 1908, the publication of "An Experiment With Descriptive Mineralogy" issues began.

From the beginning of the 20th century, Vernadsky occupied an important place in the scientific community of Russia. From 1898 until 1911, he was a professor at Moscow University, an assistant of the rector, and one of the founders and a professor of the Shanyavsky University. In 1906, Vernadsky was elected junior research assistant at the Imperial Academy of Sciences and appointed the head of the mineralogical department of the geological museum. In the same period, Vernadsky formulated basic ideas and problems of geochemistry and carried out the first systematic research of the elemental structure of the atmosphere, hydrosphere, and lithosphere. From 1907, Vernadsky carried out geological research of radioactive elements, thus starting radiogeology in Russia. He was one of the first to see it as a powerful means of providing people with unlimited energy.

In 1902, Vernadsky started a course of lectures on the history of Russian science. From that time, historical-scientific issues became an essential part of his research. In 1902, his historical-scientific study "On the Scientific World Outlook" came out. Later, he published "Studies on the History of Natural Science in Russia in the 18th Century," "The Academy of Sciences in the First Century of Its History," studies on the history of crystallography and soil study, and articles devoted to outstanding Russian and foreign scientists. In his historical-scientific works, Vernadsky showed the continuous transformation of the world pattern and change in the value of obtained facts and conclusions, predetermined with a complex of cognitive and social-cultural factors. He also proved the originality of the Russian science and also the necessity to follow its age-old traditions. The history of science became for him a source of a better understanding of the biospheric evolution and scientific development as its natural continuation.

Political and Scientific Organizational Activities

In the prerevolutionary years, Vernadsky actively participated in social-political life, which was tightly

connected to him with an effort of turning the biosphere into the noosphere. In 1891 and 1892, together with a famous writer Leo Tolstoy, he founded a social fund for helping the starving in the Tambov region. In connection with the students unrest at the end of the 19th and the beginning of the 20th centuries, Vernadsky spoke in support of the reestablishment of university autonomy and regulation of the power of police inspectors at the universities. He worked out a project of the higher school reform (1901). At the time of the bourgeois-democratic revolution (1905–1907), Vernadsky took part in the organizing of the Academic Union, which demanded political liberties, constitutional monarchy, democratization of the higher school, abolition of censorship, and foundation of professional political unions of intelligentsia and nonmanual workers. At the constituent meeting of the constitutional-democratic party in October 1905, he was elected a member of the central committee. He was an active advocate of an agrarian reform, helping the starving, abolition of the death penalty, and general political amnesty. In March 1906, Vernadsky was elected as a member of the State Council on behalf of the academic curia, and in July, 1906, he resigned as a token of protest against the dissolution of the State Duma. For the second time, he was elected a member of the Council in January 1908. Together with other professors, he left Moscow University in 1911, protesting against the reactionary politics of People's Enlightenment Minister Lev A. Kasso.

In 1911, Vernadsky moved to St. Petersburg, and in 1912, he was elected as an ordinary academician on mineralogy at the Imperial Academy of Sciences. In 1911 to 1914, he organized and headed several academic radium expeditions to the Urals, Transcaucasia, Middle Asia, and Transbaikalia; organized a radium committee (1910) and mineralogical and radiogeological laboratories (1911); and conducted a reorganization of the geological museum on the principles of evolutionism. Vernadsky called for a radical reform of research. The government supported his idea to create the Lomonosov Institute, but World War I, which soon erupted, buried the project. Vernadsky understood that without the backing of scientists, Russia was doomed to defeat. In October 1915, he became a member of the State Council once again, and in 1916, a member of the economical commission committee of the Russian Parliament economical committee, included in the parliament assembly of the Entente.

In 1915, together with other science leaders, Vernadsky organized and headed the Committee for the Studying of Productive Forces of Russia (*Komissiya po izucheniyu proizvoditel'nyh sil Rossii*, or KEPS), which became the base for several dozen scientific institutions in St. Petersburg. Some members of the Cabinet of His Majesty the Emperor, of a number of civil and military ministries and committees, and many scientific and scientific-technical associations of Russia were among the members of KEPS. KEPS promoted the creation of a base of raw materials and minerals of the country and working out the scientific-organizational approaches to the study of source potential of the regions. In 1915 to 1917, KEPS participated in the publication of the magazines *Nature* and *Productive Forces of Russia* and, organized 14 expeditions to different regions of the country. In 1916, Vernadsky offered a plan of establishing a network of state scientific research institutes, and at the end of 1917 and the beginning of 1918, an institute of physical-chemical analysis and an institute for the study of platinum and other precious metals were organized. Other projects were fully realized in the Soviet period.

The work in KEPS stimulated Vernadsky to develop systematic research in the field of biochemistry, the theory of living substance and the biosphere. In 1916, he started working out the foundations of biogeochemistry, studying the chemical structure of organisms and its role in atoms molecular migration in the geological coverings surface of the Earth, and transformation of the atmosphere, the hydrosphere, and the lithosphere.

After the February Revolution of 1917, Vernadsky upheld the policy of the provisional government to continue the war and actively came out in favor of federal system in Russia. He was chairman of the committee for the academic institutions and scientific enterprises at the Ministry of the People's Enlightenment, and an assistant minister. Vernadsky actively participated in organizing a free association for the development and spreading of positive sciences, in working out plans for creating a network of universities and research institutes, as well as new academies in Siberia, Georgia, and the Ukraine. After the October Revolution, Vernadsky became a member of the Small Council of Ministers, and on its illegal meeting on October 17, 1917, he signed an "Appeal to the Citizens of Russia," which declared the Bolsheviks' seizure of power illegitimate. Hiding from arrest, Vernadsky left

for the south of Russia, where he went through all the horrors of the civil war and repeated change of power, and came to the conclusion that the Russian people were not ready for democracy. From that time on, he kept away from politics.

During the civil war, Vernadsky was one of the founders and the first president of the Ukrainian Academy of Sciences and the rector of the Taurida University. After the Crimea had been captured by the Bolsheviks in the spring of 1921, Vernadsky returned to Petrograd, where he was arrested for a short while, but was quickly set free. He continued as head of the council of KEPS, headed both the State Radium Institute, which he had also founded, and the Committee for the History of Knowledge. He supported the studies of the atomic nucleus, aiming at the usage of the radioactive decay energy. At the same time, Vernadsky conducted intensive biogeochemical research and prepared a vast manuscript, “Living Substance,” (which came out finally in 1978). Vernadsky presented in it the first comprehensive conception of the leading role of the organic world and human beings’ activity in the transformation of the biosphere. The first results of his research were published in 1922 in *Chemical Structure of the Living Substance*, and also in 1922, *Beginning and Eternity of Life*.

The Theory of the Biosphere and the Noosphere

From 1922 to 1926, Vernadsky was abroad, giving a course of lectures at the Sorbonne, working at the mineralogical laboratory of the natural history museum and at the Pierre Curie Radium Institute, trying to find the funds for organizing an international institute for the study of living substance. In 1924, Vernadsky published *The Studies in Geochemistry* in French, in which he gave for the first time a systematic account of his biogeochemical views. In 1926, Vernadsky returned to Leningrad and published his famous book *The Biosphere*, translated into French in 1929. He organized a department of living substance, which was transformed into a laboratory in October 1928. In 1933, Vernadsky headed the meteorite committee at AS USSR.

At that time, Vernadsky formulated the main principles and problems of biogeochemistry; created a theory of the biosphere and its evolution; set problems and began quantitative research of the elemental

structure of living substance and its geochemical functions; and determined the role of individual species in the transformation of energy in the biosphere, in geochemical migrations of elements, lithogenesis, and mineralogenesis. Vernadsky outlined the main stages of the biosphere evolution and its basic patterns (expanding of the life zone, increase of accumulated solar energy in the surface coverings of the Earth, intensification of biotic circulation, growth of biodiversity and informational capacity of the biosphere, cephalization, or steady growth of consciousness in animals’ progress).

Guided by the idea of Edgar Le Rou (1927), at the end of 1930-s, Vernadsky formulated a hypothesis of an inevitable conversion of the biosphere into the *noosphere*, i.e. the sphere of mind, and gave a brief characteristic of its features. Earlier, he had been proving the possibility of the autotrophic existence of man (1925), that is, the possibility of man’s starting to live on artificially synthesized food thanks to the usage of immense reserves of nuclear energy. Vernadsky was sure that humans would become the most mighty geological power, capable of determining predestining the further development of the Earth and its organic world.

Vernadsky understood that the development of science in the Soviet Russia was possible only under state support, and he did his best to strengthen scientific potential of the country, believing that the future belonged to scientists and the communist regime would transform under the influence of the scientific progress. He was one of those who agreed to the loss of autonomy of the AS USSR in exchange for providing it with significant material, financial, and human resources. Although he held the position of head of a number of academic institutions in Leningrad, Vernadsky left for Moscow because of the move of the academy to the capital, owing to the decision of SNK (Soviet Narodnyh Komissarovm, a Council of People’s Commissars) and Politburo CK VKP(b) (Central Committee of the All-Union Communist Party of Bolsheviks). But he held the position of the head of a number of academic institutions in Leningrad. In 1941, together with other academicians, he went into exile in Borovoe, Kazakhstan. In 1943, he was awarded Stalin’s Prize.. Half of it, he gave to the defense fund, and the rest, he distributed among his needy friends.

During the period from 1920 to 1945, penal institutions more than once prepared the materials about

Vernadsky's supposed participation in various anti-Soviet saboteur activities. To save his students, followers, friends, and staff from repression, Vernadsky sent dozens of intercession letters to the Presidium of the Supreme Council of the USSR, to the SNK, to the Office of the Public Prosecutor of the USSR, and to the People's Committee for Home Affairs.

Vernadsky abruptly changed his attitude toward the Bolsheviks in the middle of the 1930s, when the rhetoric of proletarian internationalism and class struggle was replaced with the ideas of concentration on the interests of the state, nationalism, and patriotism. He also liked the slogan about transformation of the USSR into the world scientific center. With the turn of the USSR into a successor of the Russian empire, he started viewing Bolsheviks as politicians who had managed to retain national independence of the country and return it to a merited place in the world. Vernadsky understood that the positive changes were bound up with the labor of millions of convicts. He believed that their work was "in the interests of the state" and that thanks to repression, the social and intellectual power of the masses could be better revealed. Most of all, he feared then that exterior forces would try to destroy "the communist Russian state" or would make it backslide from its modernization policy.

These very years became the golden age for the "scientific empire" of Vernadsky. He was the head of several academic institutions at the same time. There were dozens of venerable scholars among his followers, and still more ahead. In 1938, Vernadsky wrote about the accordance of his biosphere ideas to with the theoretical socialism of Karl Marx and Friedrich Engels, and he started to treat the October Revolution as an event of geological scale, which had "begun the transition to the state system of conscious realization of the noosphere." Vernadsky saw the alliance of Great Britain, the USSR, and the United States and their struggle with the totalitarian regimes in Germany, Japan, and Italy as a guarantee of the victory of mind and democracy. He assured that "The ideals of our democracy are in harmony with spontaneous geological process and laws of nature." But what democracy did he consider ours? "Western" or "Soviet"? This is not clear from the last article published in his lifetime and written for publication not only in the USSR, but in the United States. It contained an outline of his ideas about the noosphere as the final stage of the development of the biosphere,

directed by society on the basis of the laws discovered by scientists.

Vernadsky died on January 6, 1945. He was sure that the coming victory over Hitler's Germany would hasten the transition from the biosphere to the noosphere. He was buried at the Novodevich'ye cemetery.

Renaissance

The renaissance of Vernadsky's ideas came in the 1960s, first in Russia, then in the West. Since 1993, *The Biosphere* has been published four times and *The Scientific Thought as a Planetary Phenomenon* three times in Italy, Spain, Germany, France, and the United States. His ideas were used in the constructing of closed ecosystems in space flights and in the grand project of creating an artificial biosphere (Biosphere-2) in Arizona. Vernadsky's fate is typical for a scientist who started before the Revolution, then integrated into the Soviet regime, seeing it as a patron of science and the successor of the imperial ideology. Like other Russian scientists, Vernadsky treated science as means of serving the state and man, considering it the source of social and economical progress. His ideas and conceptions have gotten wide recognition in the world, and have become one some of the theoretical grounds for the study of the history of humankind, the biosphere and its evolution, and for working out the measures of environmental protection. His ideas of the noosphere were further developed in the works by of Pierre Teilhard de Chardin.

VERNE, JULES (1828–1905)

In the mid to late 19th century, Jules Gabriel Verne brought to the world an innovative approach to writing that was adventurous and romantic, yet scientifically sound. As the author of more than 60 novels, nearly 20 short stories, 30 plays, and various geographical works and opera librettos, Verne, along with H. G. Wells, is rightly credited as being a founding father of science fiction.

Born in the coastal town of Nantes, France, in 1828, Verne was heavily influenced in life by a family tradition of seafaring. He went so far as to run off to be a cabin boy on a merchant ship, but was returned to his parents who sent him to study law in Paris in 1847. While in Paris he became enthralled with the theater and began writing plays, the first of which was published in 1850. His father, who was extremely displeased with Verne's decision because of his desire for him to continue his study of law, subsequently cut off his financial support. As a result, Verne began selling his stories to make ends meet.

While in Paris, Verne married and gained two stepdaughters whom he also needed to support. He thus continued to write and research a variety of subjects including engineering, astronomy, and geology. His first novel *Five Weeks in a Balloon* reflected the fruits of his labor and led to a series of well-received books including *A Journey to the Center of the Earth* (1864) and *20,000 Leagues Under the Sea* (1870). It was not until he published *Around the World in Eighty Days* (1873), however, that he became a major success. The book was extremely popular and published in several languages. He continued writing and in the mid-1870s, a stage play was made of *Around the World in Eighty Days* that became hugely successful.

Verne's ability to intricately describe the scientific advances of the day and inject them into his stories

(often using a “travel book” approach) widely appealed to readers in the late 1800s who were enthralled with global exploration and scientific progress. Although he was not trained as a scientist, he conducted meticulous research to make his books as realistic as possible. Combining adventurous stories with science fiction, Verne led readers on a voyage that seemed both plausible and genuine.

Today, his ideas cannot simply be considered fantastic or entirely fictitious, for they led Verne to postulate that there would even someday be vessels in the sky (*Robur the Conqueror*, 1886). His efforts to meticulously describe adventurous scenarios using modern science while making it understandable to a general readership is one of his greatest accomplishments and laid the framework for a new genre of writing that has inspired countless new achievements in writing and science.

Vikings, Norsemen, or Northmen were a successful group of marauders and conquerors who expanded their influence over much of Europe, parts of the Middle East, and as far east as Russia. These groups of Scandinavian clans rose to prominence during the late 8th century and continued to be a part of Western destabilization until the late 11th century.

The common name of these people has its origins in how they were seen, the word *vikingr* was the name given to a person who would plunder. The word may have a deeper origin in the word *vik*, in which case *Viking* would roughly translate to “the men of bays (or coves),” referring to the bays and coves found in abundance on their homeland’s coasts. The people known as the Vikings come from the region that currently includes Norway, Sweden, and Denmark. The Norwegians drove west into the Atlantic and the British Isles, while the Danes pushed south into the Mediterranean and Southwestern Europe and the Swedes pushed east into Russia. Seldom during the Viking Age did these Scandinavian men see any kind of national unity that could raise an army large enough to undertake the large tracts of land that they were raiding in one fell swoop. Rather the raids were held on a much more loosely based group of organizations created from fragile regional governments.

Viking incursions into Europe probably began in the late spring of 789, when three longboats landed on the shore of Dorset in the kingdom of Wessex. On June 8, 793, a Norwegian party assaulted a monastery at Lindisfarne off of the east coast of England. The islands of Ireland and the mainland of Scotland came under attack during the late 790s. To increase their range, permanent settlements were established. By 840, settlements had been built on Ireland and in Northern France, from this point until the late 9th century raids reached their peak of activity. By channeling the numerous rivers of Northern

France and of Western Germany, the sleek and agile Viking longboats were able to maneuver their way as deep as Paris. By the year 880, the only Anglo-Saxon kingdom that had not fallen to the Vikings was Wessex. For the time the Danish invaders were satisfied enough to keep the eastern third of England, which then became known as the Danelaw. By the year 911, the Swedes (otherwise known as the Rus) had worked their way through the Baltic Sea, down the Dnieper, through the Black Sea and into Constantinople (modern Istanbul). The Viking intrusion into Russia, violent as it may be, seems to have had more of a basis in trade rather than plundering; grave evidence points to contact as far back as 650. As a result of unsuccessful moves on Constantinople a treaty in 911 provided that Rus soldiers were admitted into the city guard. At the same time in France Norwegian leader Rollo (Göngu-Hrólfr), after a series of attacks on the French countryside (notably one unsuccessful on Chartres) worked out the Treaty of St. Clair-sur-Epte (911 AD) with King Charles the Simple. The treaty granted the lands that would later be called Normandy (it quite literally means the “land of the Northmen”).

While the Danes and Rus were taking the continent of Europe in the latter half of the 9th century, the Norwegians were focusing on Atlantic islands. Although accounts vary, most place the colonization of Iceland sometime between the years 890 and 910, leading to full occupation by the year 930. Icelanders would like to point the tyrannical rule of Norwegian King Harald Finehair as the reason for emigration to Iceland; however, this is doubtful seeing as he would have been too young to have ruled during colonization. It is more likely that population pressures combined with land shortages made the relatively unpopulated and mostly free Iceland appetizing for colonization. In 982, Erik the Red was banished for 3 years from Breidafjörð for a slew of killings. This was the third such banishment he had received, the first two coming from his homeland Norway and the third in Breidafjörð, Iceland. Erik decided to go in search of lands that had been sighted some 50 years prior by a Norwegian sailor. What he found he named Greenland. For the next 3 years, he explored the coast, plotting out important stores of natural resources and lands that would be suitable for farming. When his banishment had ended, he returned to Breidafjörð to gather those who would be needed to colonize the island. In 986, he returned to Greenland with

450 people and 14 ships (of the original 25 to set sail). Soon the colonies would expand to 3,000 people.

Meanwhile, as the Norwegians were discovering for themselves the Americas, Danish Vikings sought one last major conquest of England. In the year 1066, the death of the English King Edward the Confessor left a power vacuum in England. The sixth-generation descendant of King Rollo, William the Conqueror, led the forces of Normandy to victory in the Battle of Hastings. This established the foundation of the modern English monarchy and also marked the beginning of the end of the Viking's destabilizing impact on Europe. Not once since has the mainland of England been successfully invaded by a foreign power.

Despite the common perception, Viking society was not entirely composed of marauders and pirates. There existed varying degrees of morality, order, and law depending on exactly where an individual lived

and to what distinct social class he or she belonged. There tended to be a diametric opposition between those who lived in the inner rural areas and those on the edge of their controlled territories. The common perception of a violent culture was dictated not by the writings of the Vikings, which were scarce, but rather by those from the cultures that came into contact with them, contact usually being a direct result of Viking exploration and raiding. However it should be noted that those who did the exploring were not indicative of the typical Norseman, in fact they were the exact opposite. The average Viking was more likely to have been a rural farmer who lived with an extended family. Each farmstead was headed by a patriarch who obtained his power and wealth through a complex system of inheritance.

Social Classes

Within Viking society there existed a rigid social structure that vaguely resembled feudalism. The bottom class consisted of slaves (sometimes called *Thralls*), who were typically debtors, criminals, and prisoners of war. These slaves were typically regarded as being property, not human beings with legal rights. The slaves did not have the

right to debate or vote in the local assembly (the *Thing*). However there were instances in which a slave had a greater degree of legal power than a freeman: For example, a slave would be allowed to kill on behalf of his wife, even though she was a bondmaid, but a free man could not kill on behalf of his bondmaid (the dual meaning of bondmaid allows for an ironic interpretation). There were cases in which a slave was able to work his way out of slavery. This implies that the slave must have had certain rights to his own property and some way to gather sufficient funds. Other ways of escaping the slave class include being granted freedom by one's master and scoring a kill in combat.

The next class up consisted of the *Karls*, which could be described as the peasant class. The majority of the population was derived from this class of men, for it was mainly this group that cultivated the food supply. Every sort of diversified laborer whose talents would be applicable to everyday life was found in this

class: farmers, traders, soldiers, artisans, and so forth. Lawyers and practitioners of medicine could also be found in this class. These jobs, however, were not as frequently used for gaining the stable income as they are today, thus these jobs were practiced part-time by, most likely, farmers and traders. Most of the law at the time was not written down, but instead it was handed down in an oral tradition. Master lawspeakers would take on apprentices who would spend a couple of years memorizing the law. Some tended to be more apt at reciting the law; these men would be selected to be sent to the Thing. The better one was at reciting the law, the more clout one carried. Those with the highest degrees of respect would be used in settling legal disputes. Upon returning to a village from the Thing, a lawspeaker was expected to recite to the men of the village all of the new laws that had been adopted. However every free man, not just lawspeakers had the right to vote and debate in the Thing. Only the richest of the Karls held fertile land, and even then not every Karl held land. The only real measure of wealth was land, for there did not exist large enough governments to establish any kind of stable currency.

Should a Karl acquire enough land and clout, whether it be through force or by his personality, he could raise himself to the status of *Jarl*. These men made up the nobility; akin to local warlords, they could exact tribute and organize raiding parties. This is typically the highest level that Vikings could raise themselves to, for the political climate of the region was far too unstable to maintain large monarchies. Two major challenges that faced the would-be kings included a complex and therefore weak system of inheritance in which many challenges to the throne would arise, and the lack of any long-standing dynasties from which a ruler might claim legitimacy. So often the test for leadership came down to feats of strength and personality.

Religion

The Viking religion, like other polytheistic religions before it, did not adhere to one particular doctrine or order of gods. Many of the gods that the Vikings worshipped were subject to public opinion, and over time one god might fall out of favor, only to come back again in another form with a different name. The fluidity of their religion has been described as being the byproduct of having an oral tradition, rather than being written down like the major world religions that

have survived to this day (the Islamic Koran, the Christian Bible, the Jewish Torah, and others). What is known of Vikings and their religion is mostly derived from foreign observers and the sagas, which were made some centuries after their fall from prominence in the 12th century.

Some of the more stable and high-ranking gods included Odin, Thor, Loki (who was actually a giant and companion to Thor), and the twin gods Freyja and Frey. These gods and many others were employed through a series of myths to explain many of the phenomena of the natural world. According to Norse myth, the universe does not exist as we comprehend it, but rather the universe is composed of several “worlds,” such as the opposed worlds of fire and ice. Furthermore, the earth itself is said to be the back of a giant coiled serpent. Two major tales included the foretelling of the end time, called the *Ragnarok*, and Odin’s sacrifice. The latter told of how Odin hung himself from the world tree to gain the knowledge of the mystical runes. He also sacrificed an eye to drink from the fountain of Mimir such that he would gain complete and total wisdom. These stories were each designed to convey a single message or groups of messages, so they sometimes contradict each other. To strike a deep chord with the audience, these stories were often told as gruesome and violent.

Vikings felt that the gods and spirits ruled over almost every aspect of their life. This animistic belief dominated many aspects of Viking life; for example, small pendants in the shape of Thor’s mighty hammer were worn by many. These pendants were thought to be useful in invoking the help of Thor, who is often seen as a hero to peasants and the unfortunate. Viking belief held that invoking the aid of the gods was necessary for all functions of life to be successful.

Rituals involving the daily life of a farmer were typically held by the women of the household. Animal and human sacrifices were not the least bit unusual: Ragnar, a Danish leader, hung more than 100 French as a sacrifice to Odin during a raid on Paris. Also included in their religious life was the use of small statues that represented a particular god, and chanting, which, like runes, was considered to have inherent magical properties.

Runes and Language

A rune is a special type of writing symbol that can be either a letter or a word, and in many cases can have

multiple meanings. Most runes were carved, and as a result they were created from a series of lines (for it would have been too difficult to carve a curve in a piece of wood or stone). The Futhark (the name of the runic alphabet) lacks some of the traditional vowels, and therefore the runes cannot be arranged to make all possible word sounds, making translation very difficult. Furthermore most of what was carved was probably done in wood and has not survived the ages. Only a handful of rune stones still exist. Much of what is said on the rune stones consist mainly of short sayings, and many of them are just dedications to the fame and glory of a loved one, that person's family, and of course the engraver. Despite the belief in the powers of runes, not many Vikings were literate. This too detracts from the availability of primary accounts of Viking law, culture, and military action.

Much of Viking culture has its roots in Germanic tradition. The god Odin, for example, has a direct corollary whose name is Woden (pronounced Vo-den). In addition to religious contributions to Scandinavian society, the peoples of Germany provided a linguistic touch. An example is the word *geld*, which means money in modern German, and was found in the word *heregeld*, which meant army tax. For the aforementioned reasons it is difficult to distinguish between what can be considered to be pure Norse beliefs and what was added on as an embellishment of history or a by product of the Christian influence.

Valhalla was a heaven reserved for the bravest of Viking warriors. In their afterlife it was thought that one could feast, drink, and fight all day long without any consequences: If one should die in a drunken frenzy in Valhalla, one would rise again the next day with no wounds or hangover. However it is now believed that Valhalla was a compromise between the Christian notion of heaven and the ideals of the Vikings, ideals that included their perpetuation through their legacy or fame, fame sought usually through battle and kept for the ages on the runestones.

The Vikings were famed for their skill as both sailors and warriors. Their shallow, sleek hulls, combined with the dual power sources of wind and oar, made the Viking longboat one of the most feared sites in any harbor. The small frame of the ship made it more maneuverable than most other ships of the time, and the dual power made it faster. This combination of speed and maneuverability allowed Viking warriors to make raids deep into Europe. The Viking sailors who set sail from Greenland and ended up in America had

very few tools in terms of navigation. By modifying fishing boats with sails (thus creating the longboats), they were able to add range to their voyages. Although Vikings most likely used the altitude of the Sun and Polaris (the North Star) to determine their latitude, little could be done to determine longitude. They were not without resources: The path of clouds, birds and other wildlife, and debris in the water all were used to detect the proximity of land. These skills enabled the Vikings to consciously make long sea voyages, like the one that landed Erik the Red in Newfoundland.

The most significant piece of evidence in the Americas for the Viking encounter was found at L'Anse aux Meadows, Newfoundland, Canada, in 1960. Most of what remains of the Viking settlements are the foundations of their buildings and the trash that they threw away. Small circumstantial pieces of evidence were found such as clothing pins and other such trinkets. The most notable leftover piece would have to be an iron forge, a large piece of equipment that would not have served any purpose for the natives, who had not previously been known to practice iron smelting. Carbon dating confirms that these remnants date from the Viking era, about 1100 AD.

A village is a relatively stable human community, in terms of location and composition, that is generally

larger than a camp or dispersed hamlet but is smaller than a town or city. Some villages, however, only exist for a few months, as they represent a phase of an annual cycle (for example, the band villages of Kirghiz herders in central Asia). Although the term is commonly used for small agricultural communities, it can also be applied to communities that engage in fishing or other activities such as the production of handicrafts, or that have mixed economies; the latter, in fact, is increasingly the case in many parts of the world. Due to this diversity, it is not always easy to distinguish unequivocally a village from other types of communities.

Anthropologists have long debated the origin and growth of the village. Typical questions have been: Did the village arise because of settled agriculture with a degree of economic specialization, the advent of private proprietorship of land, growth of seigniorial power, or because of consolidation for mutual protection? Did some hamlets coalesce into villages while others did not? Until recently, the emergence of villages was regularly associated with the Neolithic Revolution (dated to about 10,000–12,000 years ago). The assumption, promoted by V. Gordon Childe's work, was that humans became more sedentary as they moved from food collection to food production because settled agriculture and the domestication of animals require close contact with fields and herds. As a result, agriculture and village life were considered to go hand in hand. Today many archaeologists have parted company with this model as new research and restudies of former key sites, such as Çatalhöyük, located in central Turkey and about 10,000 years old, point to a more nuanced and complex interpretation.

In southwest Asia, Natufian village sites dating to about 11,000 years ago provide good evidence for a preagricultural tradition of village life based on hunting and the collection of wild grains and nuts. Current archaeological work at Çatalhöyük, some of it spearheaded by Ian Hodder, suggests that this perhaps was an overgrown village without advanced agriculture. The people who inhabited the site depended to a large extent on wild plants and animals, even though they did tend some livestock and grew some crops. Similarly, Asikli, a Central Anatolian site about 1,000 years older than Çatalhöyük, was a large stable settlement with a population that relied mainly on hunting and gathering. In sum, in the Near East some villages emerged before agriculture or before agriculture became the main subsistence strategy. All

of this suggests that the transition from foraging to domestication took various paths and that some peoples developed mixed economies that combined reliance on wild and cultivated foods (and, maybe, with periods of no cultivation). This transition, likewise, included various types of communities that reflected different degrees of mobility and population densities. Research in other areas of the world besides the Near East (for example, South America, Mesoamerica, North America, and China), has furthermore revealed that people domesticated plants well before farming villages were established. Therefore, though settled life and agriculture are related, they are not necessarily coterminous.

Yet, many of the early domesticators did become settled agriculturalists by about 10,500 years ago in the Near East, 7,000 years ago in China, and later in Africa and the Americas. On the whole, the early settlements they constructed were small and dwellings were situated in close proximity to each other, perhaps for sociability, defensive purposes, or both. Even though the expansion of many of these settlements—from hamlets to villages—roughly coincides with the rise of agriculture, it is not clear whether agriculture fueled settlement growth or whether other factors were involved. As the archaeology and ethnohistory of California and the Northwest coast of North America reveal, substantial housing can exist without food production.

Because villages were the prevalent type of community settlement in most of the world until the Industrial Revolution and the subsequent spread of urbanization, many social scientists of the 19th century regarded the village as a universal stage in human evolution. The scientific study of the village dates to that century, and it by and large centered on Feudal Europe and land tenure rules, systems of field rotation, the legal status of villages, the emergence of village fairs and markets, and the growth of towns. Sir Henry Maine (1822–1888), one of the early writers on this topic, attributed the emergence of villages to the evolution of more elaborate political structures, which in turn altered land ownership. Instead of searching for absolute theories of origins, which were quite popular in the 19th century, contemporary anthropologists concentrate on the structure, function, and networks of village communities and their links to regional, national, and global economic, political, and social processes. Neoevolutionary theorists, though, remain interested in village formation

Source: © iStockphoto/Kate Borland.

and its relation to social evolution, in particular, its relation to the evolution of human sociability, internal–external conflicts, leadership, and institutions of authority. Archaeologists still debate how best to document, archaeologically, village formation and its fissioning.

During much of the 20th century, anthropologists spent considerable time debating the nature of social relations within villages and between the village and the outside world. Were villages teeming with social tensions or did they have less social strife than towns and cities? Why did some villages seem more open to external influences whereas others appeared to shun them? Most of these studies were part of a broader concern over peasantries, culture change, and the impact of economic development in the Third World. These studies often established a contrast between traditional villages and modern or modernizing villages. The traditional village was considered subsistence-oriented, egalitarian, community-oriented, religious, and peaceful. Influenced by commercialization and commoditization, these villages were transformed

into the modern type, which was characterized by dependency, socioeconomic stratification, individualism and competition, jealousy and strife. This characterization cannot be divorced from romantic images about village life and earlier, yet still influential, speculations about social evolution. Persuasion and egalitarianism, not coercion and stratification, have been seen as the rule in early village society due to conditions of low population density, which allowed for the option of fissioning when conflicts arose.

Some also attribute this depiction to a conceptual and methodological pitfall of classical anthropology, namely, to its great emphasis on the study of autonomous, small-scale societies, and to the transfer of concepts and methods designed for the study of such societies to the study of transitional and large-scale societies. Robert Redfield's earlier work among peasants in the village of Tepoztlán, Mexico, reflects this difficulty. In his later work, however, villages are no longer conceptualized as isolated and autonomous units but as part of a folk–urban continuum in which human communities range from simple to complex.

According to Redfield's later view, communities along this range exchange cultural traits and cultural brokers function as mediators between the different types of community and their traditions. What was lacking in Redfield's theory was an explanation for how macro political and economic processes shaped the various communities. Julian Steward's *The People of Puerto Rico* also attempted to deal with the methodological problems associated with the issues of scale, modernization, and social complexity. Perceiving villages as part societies, like Redfield, Steward—influenced by his views on cultural ecology—related village types to local ecological factors and to their degree of vertical and horizontal integration to the nation. Eric Wolf, influenced by Redfield's and Steward's work, similarly constructed a typology for peasant villages that was meant to emphasize degree of interaction with the outside world because he believed that the peasantry became more heterogeneous under the influence of the global economy. Wolf's classification had two main types, closed and open communities, besides other possibilities. In closed, corporate peasant communities, people labored primarily for subsistence instead of the market, and land was held communally. Also, there was a great deal of internal solidarity and homogeneity. In open communities peasants were drawn into the market and land was held individually; thus, individualism and strife were salient factors. Wolf's two main types fed directly into the dichotomy of traditional versus modern village even though he was cognizant of the processes at work.

Over the years various scholars—not just anthropologists but geographers, sociologists, and historians—have challenged the traditional versus modern typology. Several have argued that inequality, at times based on prestige, power, and access to nontangible ritual wealth, was part of village life in various areas even before contact with Westerners or the advent of mercantile capitalism and colonialism. Differential access to land and village labor—frequently conditioned by native social and symbolic constructs—at times contributed to inequality in some places, such as Java. Critics have also charged that if some households seemed to labor to benefit their community, it was because of an overlap of interests with those of the wider community and not because self-interest and individualism were absent. In addition, historical and archaeological work revealed that villages far removed from urban centers were often impacted by

the political and economic activities of states (for example, 19th-century rural villages in Siam, present-day Thailand), a line of inquiry that Wolf paid much attention to during his later work. Actually, the interdependence between villages and quasi-urban and urban centers contributed to the structure and particulars of village life. Some villages, regarded as stable and identifiable units since time immemorial, were colonial creations. For instance, in Southeast Asia and Latin America, colonial powers combined and divided indigenous communities to create villages, facilitating control over labor, lands, and natural resources.

Villages remain the main type of rural settlement in much of Africa, Asia, and Latin America. Today, however, most villages maintain strong ties to one or more urban centers, are linked to the global market, and may contain diverse residents that migrated to the area. Televisions, radios, cell phones, computers, missionaries, tourists, traders, and nongovernmental organization (NGO) workers help maintain these connections; so do migrant labor arrangements and improvements in systems of transportation, the latter often encouraged by NGOs, foreign aid to developing countries, and the local government's (or residents') desire to embrace modernity, the global market, and the technological devices all of this brings. In remote places like Nepal, wireless Internet technology is being used to link remote villages and enable residents to sell goods online. Village members are also able to communicate with coresidents who are grazing yaks in distant locations far away from the village. Due to all of this, some scholars contend that modernization may actually lead to greater levels of political and economic participation in villages. Increasing economic differentiation and specialization, though fostering dependency, can promote cooperation. In addition, the recording of village census data and the construction of village schools, infirmaries, collective water pumps and storage tanks, among other projects, may be contributing to a coherence that was lacking or minimal in the past. In sum, modernization does not necessarily undermine a village's communal orientation, but may actually strengthen or create it.

In contemporary industrial and postindustrial nations the concept of the "village" remains important even if it is no longer part of everyday reality. Ideas about cultural and ethnic identity, place, history and change, economic production, and local political administration are wedded to the concept. Hence, the study of post-peasant villages in many areas (for

example, France, Italy, Japan, Spain, and Portugal) could yield significant theoretical and methodological insights for the study of contemporary ethnicity and imagined communities, historicity, culture change and continuity, and the evolution of institutions of local government.

In some parts of the United States, for example, New England and New York, the term *village* may refer to a unit of local government. Today, however, “the village” usually denotes the social and commercial hub of a town and is readily distinguished by its pleasing architecture, diverse shops and coffee houses, and pedestrian-friendly walkways. The term can also be used in whimsical ways (for example, “the punker’s village”), to refer to a residential district within an inner city usually composed of people with similar cultural backgrounds or interests, such as Greenwich Village in New York City, or to conjure up romantic notions or feelings generally associated with ideal village life. In truth, many small towns in the United States, villages by most standards, have been absorbed by nearby cities, suburbs, and suburbs of suburbs (exurbia). The prevalence of a basically urban-industrial civilization, frequency of residential mobility, and the global market fuels this process of “villagephagy” in the United States and sustains our longing for “uncomplicated village life.”

The desire to experience village life and its idealization are not new. During the mid-19th century, some newly rich Yorkshire industrialists (Titus Salt, Edward Ackroyd, and the Crossleys), concerned about the poor living conditions of their factory workers, promoted the idea and creation of “model villages” in England. They established the villages in the countryside because their proponents assumed that a good environment fostered good health and morals. These villages were small and were meant to be self-sufficient communities where people would work and live. Contemporary eco-villages, also known as sustainable villages, resemble these early model villages, including, for instance, the push for self-sufficiency that now has been reworked into the concept of sustainability. Eco-villages have sprung up in numerous places such as Western Europe, Australia, New Zealand, North America, and Central and Eastern Europe. They are located in both urban and rural areas and usually rely on renewable energy sources and eco-friendly architectural methods. The residents manage waste locally and engage in organic farming. For the most part, these villages support themselves via grants, donor agencies

such as the European Union, tourism, summer schools and various workshops, festive events, and volunteerism. The extent to which eco-villages in post-Soviet bloc countries can be related to former workers’ brigades and agricultural communes, and the mindset those arrangements fostered needs to be investigated.

The advent of computer networks has also enabled the creation of various electronic or cybervillages. Electronic villages can exist partially or entirely on cyberspace, depending on the activities of their “residents.” The villages have emerged because local residents wish to communicate, build, and enhance relationships with each other through computers and the Internet. Thus, most electronic villages have a private e-mail component and public forums. Most also provide on-line information about local government agencies, housing, businesses, and community activities. The electronic meeting “place” is viewed as an addition to the community’s physical places where folks can meet; people frequently meet in actual locations for social events and business transactions. Curiously, some of the most successful electronic villages in the United States are in smaller communities. A pressing need for contemporary anthropology is to understand the impact that these electronic villages have on local political and economic behaviors as well as on broader national trends. Another avenue of research would explore whether participation in electronic villages leads to changes in cultural models of friendship, intimacy and trust, accountability, community, and citizenship.

VIRCHOW, RUDOLF LUDWIG KARL (1821–1902)

Rudolf Ludwig Karl Virchow was born on the 13th of October, 1821 in Schivelbein, Pomerania, Prussia (part of Poland now), and he died on the 5th of September 1902 in Berlin. He was the only child of the treasurer Karl Christian Virchow and his wife Johanna Maria, née Hesse, who was taking care of the household and the well-being of their child.

First, he attended school in Schivelbein, and then he went to grammar school in Köslin until 1839. In the same year, he began to study medicine at the famous Pépinière in Berlin, which was a military university. In 1843, he was awarded the doctor of medicine and began to work as a military surgeon at the Charité, a famous hospital in Berlin. A year later, he was made assistant of Robert Froriep, and in 1845 he wrote his first articles, which dealt with (blood) clotting and leukemia in Froriep's *Neue Notizen*.

After finishing a further thesis (Habilitation) in 1847, he became Privatdozent, which implies the right to lecture (*venia legendi*) and can be compared to an associate professorship. In the same year, he and his friend Benno Reinhardt founded the journal *Archiv für pathologische Anatomie und Physiologie und für klinische Medizin* (Archives for Pathological Anatomy and Physiology, and for Clinical Medicine), which was later known as *Virchows Archiv*. He remained the editor until his death, and from 1852 onward (following the death of Reinhardt) he was the sole editor. For a short period of time (July 1848–June 1849), he was also in charge of the weekly magazine *Die medicinische Reform*, a journal he had founded together with Rudolf Leubuscher, and in which he already demanded that standardized medical laws for whole of Germany, a ministry for public health care, a medical academy, and a radical reform of the public health system. At that time, he also investigated a typhoid epidemic that had broken out in Upper Silesia. In the report that he wrote for the government, he suggested that a proper democracy and education for all is supposed to lead to freedom and well-being.

As Virchow was very active politically and always defending a liberal political position, he got into trouble with the government, and was eventually suspended from his post at the Charité. However, in the same year he was also offered the chair of pathological anatomy at the University of Würzburg, which was

the first of that kind in Germany. A year later, he married Rose Mayer (1832–1913). Together they had three daughters and three sons.

Not only his private but also his professional life flourished during his 7 years in Würzburg, and in 1855 the notion of *Cellularpathologie* (cellular pathology) appears for the first time, and, together with it, the concept of a new pathology. His assistant in Würzburg was Ernst Haeckel.

In 1856, Virchow accepted the offer for a chair at the University of Berlin, and he also became the director of the newly founded pathological institute. Two years later he published his most important medical work entitled *Die Cellularpathologie in ihrer Begründung physiologische und pathologische Gewebelehre*. He was elected to the Berlin City council in 1859, on which he remained active until his death. Two years later, he also became a member of the Prussian parliament, and he was one of the founders of the Deutschen Fortschrittspartei (another founding member was the famous historian and lawyer Theodor Mommsen). He was a relentless opponent in particular of Otto von Bismarck, with whom he even would have had a duel with pistols if the minister of war had not interfered. As a consequence of his political involvements, significant changes in the public health care system in Berlin took place, a sewage system was built, and a central water supply was provided. Berlin became one of the cleanest big cities in Europe. In addition, many other improvements were made, like the construction of four local hospitals, or the training of nurses independent of ecclesiastical organizations.

During the German–French war (1870–1871), Virchow organized hospital trains. In 1873, he became a member of the Academy of Arts. During that time, he dedicated himself further to the study of anthropology, taken in an extremely broad sense, as he holds that anthropology deals with the history and the future of humanity. He had already founded the *Berliner Gesellschaft für Anthropologie, Ethnologie und Urgeschichte* in 1869. At a conference in 1876 in Hamburg, he declared the goals and methods of modern anthropology in detail, and in the same year in Berlin, he gave a widely noted presentation about the anthropology of the Germans. It is interesting to note that, although he was sympathetic to Darwin's theories, he did not regard himself as a disciple of Darwin, as he explained in a speech in Munich in 1877. In addition, he also made some significant contributions to the field of archaeology, particularly in

Germany. However, together with Heinrich Schliemann, he also traveled to Troy in 1879, and because of his friendship with Schliemann and some adequate negotiations, Schliemann donated to the museum of ethnology in Berlin some of his immense treasures. From 1880 to 1893, Virchow was a member of the German Reichstag. In 1888, he traveled to Egypt together with Schliemann. At his 80th birthday, he received honors from all over the world, and in an expression of thanks he replied to all the honors he received in 1901. After fracturing the head of his femur when jumping off a tram in the Leipzigerstrasse in Berlin, he did not recover. He died on the 5th of September 1902 in Berlin.

During the 19th and parts of the 20th century, anthropology was a part of the discipline of medicine, which is the reason why it was often described as physical anthropology. Virchow also started to be concerned with anthropology via medicine. He was a humanist, and his humanism was based on the natural sciences, its authentic expression being anthropology. His understanding of anthropology was extremely broad, concerned with the whole of the human nature, which includes outer, objective as well as inner, subjective experiences. Regarding anthropology, his thinking was primarily concerned with the questions: What is the origin, and what will be the further development of human beings?

Before mentioning some of his work in anthropology, an overview of Virchow's method and his understanding of the natural sciences must be provided. Virchow had a particular theory of knowledge, which he presented in Stettin in 1863. According to this theory, scientists are concerned with facts rather than speculations, but he also stressed that it is important for them to be clear about the facts so that they can be interpreters. He regularly stressed the importance of the distinction between facts and speculations, or between knowledge and belief, and that it is necessary not to give too much weight to our speculations and not to use them for constructing a complete worldview. Facts can be reached by means of empirical experiments. Besides the relevance of the empirical data, Virchow stresses the importance of logic. Therefore, he does not refer to logic in an idiosyncratic sense, but rather to the Ancient, well-founded logic. All premises primarily need to be based on sense perceptions and experiences, but not on any kind of speculation. By means of logic, one can then infer further insights that, of course, are open to interpretation. Yet, one always has to be clear about what is an insight

and what is a speculation, and one also should not yield to the temptation to construct a system on the basis of the interpretations of one's insights. The realm of consciousness cannot be investigated thus by natural scientists, as this area is connected too closely to the individual, and therefore one cannot get facts about the deeds of the consciousness.

Because Virchow thought that there is an inner connection between all aspects of the apparent realm, he tried to establish a scientific theory that is valid for all scientific branches. He referred to that theory as *Einheitswissenschaft*, unified science, whereby he meant that the same method was supposed to be applied in all natural sciences, as all of them are supposed to look for the same thing, namely the law of becoming, and he tried to apply that theory to medicine as well. Medicine, however, is not a simple natural science. Natural sciences are concerned with bodies only, whereas medicine is supposed to deal with the laws of body and mind, but also in a solely positivist manner. Therefore, it is the highest and most noble natural science. Virchow sees a medic as a modern type of natural philosopher.

He admits that he might be wrong concerning some specific details that he had put forward, but that it is his most basic conviction, and one which he can never abandon, that human nature is unified. The same laws of life can be found in a healthy as well as ill person because it is only the manifestation of the laws that is different. Therefore, one should no longer be concerned with physiological pathology, as that notion attributes a specific ontological status to diseases, but one should only be concerned with physiology whereby pathological physiology should be a specific field of physiology. Healing, in that case, means nothing but bringing about the normal conditions of life with which physiology is concerned. Pathology deals with the altered conditions of life, and therapy with the methods of retransforming them back to normal. Virchow's categories remind one of a scheme that can be found in more traditional types of medicine that distinguishes between theoretical and practical medicine whereby the theoretical field is divided up into physiology (*res naturales*), pathology (*res contra naturam*), and hygiene (*res non naturales*), and the practical field, which includes surgery (*Chirurgia*), pharmacy (*materia medica*), and dietetics (*Diaita*).

What was lacking so far was a theory of medicine, and by this he primarily meant a pathological physiology. Anatomy, therefore, could only be the entrance

hall to authentic medicine, which is the science of healing, which again had to be founded on a complete and holistic understanding of human beings whereby one enters the realm of anthropology—a realm that is the most basic part of the medical realm. Because the fundamental component of human beings as well as of other living things is the cell, according to Virchow, he dedicated a great amount of work to that field.

In 1858 in Karlsruhe, Virchow presented the insight that life is the deeds of a cell, and that the particularities of life are identical with the particularities of a cell. He postulated that life can be explained by reference to the anatomical and chemical composition of a substance because everything that happens in nature happens in a causal and necessary manner, and this law applies to both the organic as well as the inorganic realm. Yet Virchow also stressed that he was not a materialist.

Having clarified Virchow's scientific method and the relationship of anthropology to the other sciences, some of his anthropological findings should be mentioned. Originally, Virchow held that there is a direct link between the size of a skull and the cultural and intellectual state of development of humanity. In addition, he held that not only the size but also the aesthetic qualities of a skull are relevant for one's intellectual capacities. However, the more skulls he investigated, the more he doubted these positions. As he did not wish to put forward unfounded theories, he dedicated himself to collecting empirical data, which meant that Virchow had an enormous collection of skulls. From this data, Virchow inferred that there is a distinction between the biological and the cultural development of human beings—a position that was opposed to the evolutionism dominant in Britain. Virchow's theory was based on the thesis of the unchangingness of the human race, as defended by his former pupil, the anthropologist Julius Kollmann. However, in contrast to Kollmann he did not hold the absolute permanence of human beings, but claimed that human beings could not have developed from great apes during the period of time for which we have empirical data. The question concerning the origin of human beings can only be answered philosophically; however, it was his intention to deal only with theories that could be based on solid empirical data. In principle, he acknowledged the descent of human beings from great apes as a hypothesis.

VÖRÖS, GYÖZÖ (1972–)

Gyöző Vörös is an Egyptologist belonging to the new generation of Hungarian archaeologists. In spite of his young age (born in Pécs, Hungary, January 15, 1972), he became very accomplished and well known on an international level. Vörös has spent most of his professional life in Egypt, where he was working for the government of Egypt (1994–2004). Since 2004, he has led an excavation for the government of Cyprus.

He graduated from Lóránd Eötvös University of Sciences, Department of Egyptology, Budapest (1988–1993). He had two major scholarships, one in Rome (Gregoriana) and one in Jerusalem (Hebrew University). He also graduated from Péter Pázmány Catholic University, Faculty of Theology, Budapest (1990–1993). Because architecture is a major part of his interest, he continues his studies at Budapest University of Technology, Faculty of Architecture. Vörös holds an MA in Egyptology (1994) and a PhD in History of Architecture (2001). The title of his doctoral thesis was *The Temple Architecture of Ancient Egypt*.

Between 1994 and 1998, he was the director of the Hungarian Thoth Hill Mission in Thebes, at the mortuary temple of Pharaoh Sankhkare Montuhotep III. The excavations revealed the earliest stone temple in Egypt under the superstructure of the Middle Kingdom temple. He also discovered the burial place of Sankhkare Montuhotep III, between the cliffs of the hill.

Between 1998 and 2004, he worked as the director of Taposiris Magna, 45 km west of Alexandria on the Mediterranean coast. The excavations discovered the original sanctuary of the acropolis, with both the torso of the cultic statue and the sacrificial objects of the goddess Isis. In the meantime, he identified the scene of the Fortuna Primigenia mosaic in Praeneste, which depicts the Khoiak festival of Isis in Taposiris Magna. The Hungarian Mission has completed the excavations of the acropolis in 30-field-months.

Gyözö Vörös is one of the registered survivors of the Luxor terrorist attack, November 17, 1997.

Taposiris Magna (also called Abu Sir) is situated 45 kilometers to the west of Alexandria, on the coastal dune between the Mediterranean Sea and the freshwater Mareotis Lake. The ancient city and its acropolis were founded by Pharaoh Ptolemy II Philadelphos. Ninety years had passed between Evaristo Breccia's pioneering excavations in Taposiris Magna (1905–1907) and the Hungarian archaeological mission at the site (from 1998–2004). In the middle of the 20th century, Achille Adriani launched a significant program of restoration (1937–1939), as did Jasper Brinton after him (1945–1948), but neither project was completed. Although Adriani's and Brinton's groundwork was notable, neither of them began excavations at the acropolis because there was a general agreement that the acropolis of Taposiris Magna was an unfinished construction and that it had never operated as a temple. When the Hungarian team began the excavations, this view was so universally accepted that new lexicons and summaries written about Egyptian temple architecture would always mention "the unfinished and uninscribed temple of Taposiris Magna." This official academic position was based on the mistaken premise that the floor level to be found in the courtyard of the acropolis and covered with pavement stones (excavated by Breccia) is contemporaneous with the huge temenos wall surrounding it. This led scholars to conclude that the acropolis courtyard was never home to an inner sanctuary or shrine dedicated to a cultic statue.

Drawn and photographic documentation were gathered by the Hungarian excavations in the acropolis courtyard. The floor-level foundation of the pavement stones brought to light Roman coins and potteries, making it certain that they were looking at a layer that belonged to a later period of the acropolis. At the bottom of the filling, which was homogenous, with an average height of 80–90 cm, they found the imprint of the former sanctuary. In doing so, the

Hungarian experts not only succeeded in proving that the acropolis was completed, but that they had reached a unique monument of architectural history. It transpired that a Hellenic shrine with Doric columns had once stood in the courtyard of the Egyptian-style acropolis with its pylon entrance and surrounding wall. Thanks to the imprint carved into the rock, to the remaining elements of the shrine (on one hand they came to light during their excavations, and on the other hand, 117 column drums can be found on top of the temenos wall), and to the surviving Greek architectural analogies, it can be fully reconstructed. As a result, Taposiris Magna has not only been put back on the map of ancient temple architecture, but it has been recognized as the only site of both Greek and Egyptian temple architecture yet to be fully excavated and reconstructed.

In addition to research in architecture and architectural history, the Vörös team also succeeded in presenting significant results concerning the cult of the former sanctuary. It became possible for them to prove that the acropolis was originally built in honor of the goddess Isis. The excavations brought to light torsos from the former cultic statue of the goddess carved out of black granite, as well as her sacred vessels, which her priests used in secret rituals. The cult of Isis spread across the entire Roman Empire.

Bearing in mind that Taposiris Magna was the biggest center of her cult in the Alexandria region—and so in Egypt as whole—it is no accident that in certain cities of the Imperium they not only began to worship the goddess, but also adopted the name of her cult's original location. It should be noted that sacrifices were made to the "Isis of Taposiris" on the Hellenic island of Delos just as they were by the Italici in Faesulae (today: Fiesole), on a Tuscan hilltop overlooking present day Florence.

Since 2004, Vörös has been the director of the Hungarian Mission in Nea Paphos, Cyprus.

VYGOTSKY, LEV SEMENOVICH (1896–1934)

Lev Semenovich Vygotsky was one of the former Soviet Union's most important and influential psychologists. Although he died before he was 40, and his writings fell into disfavor by Stalin and were banned until 1956, he has left a lasting mark on both American and Continental scholars in numerous fields, from anthropology to cognitive science. His most famous books in English are *Thought and Language* (1986 [1934]), *Mind in Society* (1978), and *The Psychology of Art* (1971).

Vygotsky was born in 1896 in Orsha, near Minsk in today's Belarus. Although he was a bright student and graduated with a law degree from Moscow University in 1917, being a Jew in Tsarist Russia was an obvious liability, so he had to return home to teach literature in high school. While in Moscow, however, he also attended a free university taught by professors who were expelled from their teaching posts because of their politics. It was here that Vygotsky studied psychology, philosophy, and literature, all subjects he would put to use after a turning point in his life in 1924. That year he presented a paper at the All-Russian Psychoneurological Conference in Leningrad on the relationship of Pavlov's conditioned reflexes to human consciousness. He was then immediately invited to attend Moscow's Psychological Institute, where he submitted a dissertation on the psychology of the arts in 1925.

From 1925 until his death in 1934, Vygotsky worked incessantly, creating the bulk of his canon. He attacked not only practical problems facing the new Soviet state—such as educational reforms, illiteracy, and disability concerns—but also theoretical issues in the study of society, language, and cognition. He sought to find a way for the physiological or experimental psychologists—who were largely focusing on overt behavior—to meet with the phenomenologically

or philosophically oriented psychologists—who were focusing on mental states.

Vygotsky concluded that all mental life is actually a product of social development. That is, instead of postulating, say, that children become enculturated by learning—or deciding or thinking—to conform to the social rules they see around them, Vygotsky saw society as preceding the individual by providing the conditions that allow individual thinking to even emerge in the first place. Individual consciousness, then, develops through contact with society, and is not a property an individual has in isolation. As Vygotsky wrote, “The mechanism for social behavior and the mechanism of consciousness are the same. . . . We are aware of ourselves, for we are aware of others. . . .” But these mental functions must be mediated, and Vygotsky saw tool use and the use of signs as the most essential ingredients of higher thought processes. Language, of course, is the most general of all semiotic systems, and was of special interest to Vygotsky.

But not only linguists and psychologists find refreshing approaches to old problems in Vygotsky's work. “Vygotsky managed . . . a unique approach that does not separate individuals from the socio-cultural setting in which they function. This integrative approach to social, semiotic, and psychological phenomena has substantial relevance today, a half century after his death.”

—James Stanlaw

WAGNER, RICHARD (1813–1883)

On May 22, 1813, Wilhelm Richard Wagner was born in Leipzig, Germany. He was destined to become both a supreme composer and accomplished conductor, as well as one of the towering geniuses of all time. As a child, he was especially interested in writing and the theater. Later, however, three memorable productions permanently determined his interest in music: Weber's romantic opera *Der Freischütz*, Beethoven's only opera *Fidelio*, and Beethoven's *Ninth Symphony* (particularly the choral fourth movement).

Wagner's artistic creativity was greatly influenced by Shakespeare and Beethoven. He admired Shakespeare's dramatic tragedies with their psychological orientation, and recognized Beethoven as both the master of the symphony and the founder of romantic music. Thus, by the age of 17, those elements that were to pervade his own works had already become established in his mind: music, poetry, drama, and romanticism with its emphasis on love and freedom.

While advocating political and social reforms to bring unity and freedom to the German people, Wagner himself lived in an elaborate manner that he seemed to require for his artistic creativity. He spent extravagant amounts of money on outfits of silk and velvet, magnificently furnished living quarters with thick carpets and drapes, and made extensive travels throughout Europe to take rest cures or visit wealthy supporters of his ideas. The musician also admired many beautiful women, and his frequent escapades caused more than one serious scandal in the conservative Catholic Bavaria of the 19th century.

Unfortunately, the lavish lifestyle that he demanded and to which he had become accustomed resulted in his having to leave Germany for France in 1839 to escape creditors. Although the operatic center of the

world at that time was Paris, the city neither recognized nor appreciated his musical talents. In fact, he was even sent to debtor's prison. Yet while in Paris, Wagner did complete two major works: *Rienzi, der Letzte der Tribunen* (1840) and *Der fliegende Holländer* (1841). For subject matter, he had turned to historical situations and German legends.

In 1842, Wagner was finally allowed to return to Dresden. Back in Germany, he completed two new operas: *Tannhäuser, und der Sängerkrieg auf Wartburg* (1845) and *Lohengrin* (1848). His interest shifted to the struggle for German unification, and he even associated with the notorious anarchist Michael Bakunin during the ill-fated Dresden revolution. Because of his participation in this social uprising, he had to flee from Germany to Switzerland to escape arrest. At this time, the German composer Franz Liszt defended Wagner's works and later conducted the first performance of *Lohengrin* at the Weimar Court Theater on August 18, 1850.

While in Zurich and later in Tribschen near Lucerne, Wagner began a series of prose works expounding his own theory of opera and theater. Of particular importance is his book *The Art-Work of the Future* (1849). He himself conceived of the symphonic music-drama as a synthesis of the arts, referring to this unique union as the German artwork of the future. During these years of exile, Wagner was influenced by the philosophies of Ludwig Feuerbach and Arthur Schopenhauer. He also envisioned establishing a yearly opera festival for the performances of only his own works.

Since 1845, he had been working on presenting the Germanic sagas as a series of four music-dramas dealing with Teutonic mythology. It would be the greatest task of his life, requiring a convergence of the arts that would express universal themes that focus on the emergence of humankind.

In 1859, *Tristan und Isolde* appeared and revolutionized music in general and opera in particular. It was followed by *Der Meistersinger von Nürnberg* (1867), his only comic opera. Nevertheless, it seemed that his music for the great mythological *Ring* poem he had written would not be completed. Unfortunately, the composer again had monetary difficulties and feared his great plans would never materialize. Despite all his problems, Wagner was making major contributions to music and the theater: He enlarged the size of the orchestra, introduced new instruments of his own design, expanded the musical range for both singer and instrument, further developed the use of counterpoint and dissonance, strove for dramatic as well as poetic performances of his own works, and designed his own unique opera house (a theater with a sunken orchestra pit, no visual obstructions, tiered seats, and near-perfect acoustics—he modeled it after the classic Greek amphitheater).

In 1864, there occurred a remarkable turn of events. As his generous friend and royal patron, the young King Ludwig II of Bavaria now offered Wagner all the financial assistance needed to fulfill his extensive undertakings. Never again would the once-struggling composer lack support for his bold projects.

After 29 years, Richard Wagner's masterpiece appeared as *Der Ring des Nibelungen*. It remains the largest single musical work ever written and one of the supreme artistic achievements of Western civilization. The *Ring* cycle consists of four consecutive operas:

Das Rheingold (1854), *Die Walküre* (1856), *Siegfried* (1869), and *Götterdämmerung* (1874). Together, these music-dramas tell an exciting story about Rhinemaidens, dwarfs, gods, giants, heroes, and the forces of nature. In general, one sees and hears the dramatic struggle between good and evil within a dynamic universe. To give musical unity to this vast work, Wagner perfected his use of leitmotifs within the symphonic structure of the four operas. The *Ring* cycle musical signatures represent characters, emotions, objects, or events; these leitmotifs also evolve as the story itself unfolds. In the romantic tetralogy, *Das Rheingold* comes closest to fulfilling the composer's desire to create an artistic unity of music, poetry, and drama.

Like Feuerbach, Wagner held man to be a product of and totally within natural

history. Turning to the Germanic myths, he was now able to treat universal themes, as well as express the whole range of human psychological-emotional states. Wagner was also attracted to the following aspects of Schopenhauer's philosophy: will, process, necessity, pessimism, renunciation, and cosmic unity. However, Wagner did see love as the redeeming force from the pervasive evil in the world.

There are also elements of Darwin, Marx, and Freud in *Der Ring des Nibelungen* for, as this sweeping mythological cosmology evolves, it portrays the social and psychological struggle between good and evil: The stolen, twice-cursed magic ring passes through levels of existence and pivotal events, only to be returned to the Rhine River where it had originally been placed. Essentially, the *Ring* cycle is an artistic expression of those major ideas that emerged in the 19th century and then dominated the 20th century, that is, the evolution and extinction of life forms, the ongoing conflicts among different social groups, and the psychosexual motivation of human thought and behavior.

For Wagner, *Der Ring des Nibelungen* was a unified artwork, the result being a total experience for the operagoer. The music mirrors the unconscious elements, while the drama itself represents the unfolding events of the story on the level of consciousness. The final result is a complex universe of feelings and emotions. The first complete performance of the *Ring* cycle was given at Bayreuth, Germany, in August

1876. In the history of opera, it was a tremendous success, but it was also, unfortunately, a financial disaster. Nevertheless, this work remains an unequalled achievement in Western culture.

It may be argued that Alberich's ugliness set the whole Ring cycle in motion, as it resulted in his rejection by the Rhinemaidens and, consequently, his stealing the lump of magic gold. (Interestingly enough, no single character in the Ring cycle physically appears in each of the four music-dramas.) The last word in the cycle is "ring," spoken by Hagen just before his drowning, but we never see Alberich die. Evil still lurks in the world. Of course, if this mythic reality is circular, then a new cycle will begin. In fact, this cycle may not have been the first one to have occurred.

In 1882, Wagner's sacred festival music-drama *Parsifal* was first presented in Bayreuth (it was never intended to be performed elsewhere). With this opera, the great composer had given to the world his last marvelous work. Unlike the pagan *Ring* operas, *Parsifal* embodies Buddhist and Christian symbolism as well as mysticism. The atheist Friedrich Nietzsche himself, who had once seen Wagner as the incomparable German artist but criticized the composer's growing nationalism and theatrical orientation, now rejected his all-too-obvious religious orientation in *Parsifal*. In fact, this glaring difference between Wagner and Nietzsche resulted in the abrupt break of their friendship, although there was probably a subjective element in the criticism from the still unrecognized, unappreciated philosopher.

Richard Wagner's theories and operas have had an enormous influence on music and theater. He has fascinated such diverse individuals as Thomas Mann, Arthur Rackham, George Bernard Shaw, Sir Georg Solti, Richard Strauss, and Arturo Toscanini. Each summer the Bayreuth Festival is a living monument to Wagner's awesome vision and spectacular success.

— H. James Birx

WALLACE, ALFRED RUSSEL (1823–1913)

The independent codiscoverer, with Charles Darwin, of the principle of evolution by natural selection, Wallace was born near Usk, Wales. Even as he trained for a career as a surveyor, Wallace developed a lively interest in natural history, and after he moved to England in 1844 a fortunate meeting with another amateur naturalist, Henry Walter Bates, led to organizing a joint expedition to the Amazon Basin (1848–1853) to collect natural history specimens. Tragedy struck on the way home when the ship on which Wallace was traveling caught fire and his collections were lost; but the books that resulted from Wallace's explorations caught the attention of the Royal Geographical Society, which, along with insurance monies, helped fund a further expedition to the Malay Archipelago (broadly, Indonesia) in 1854–1862.

This proved to be one of the great natural historical explorations of all time. Among many other observations, Wallace noted that the 3,000-mile-long archipelago could be divided into two distinct biogeographical regions, the "Oriental" fauna to the west of a line (known now as "Wallace's Line") bisecting the archipelago between the adjacent islands of Lombok and Bali being substantially distinct from the Australasian fauna to its east. Wallace's resulting book, *The Geographical Distribution of Animals* (1876), became a founding document of the discipline of biogeography.

During his Indonesian travels Wallace also refined an evolutionary view of life's diversity that he had been nurturing ever since reading Robert Chambers's

anonymous work *Vestiges of the Natural History of Creation* (1844). In 1855 he published a paper titled *On the Law Which Has Regulated the Introduction of New Species*, in which colleagues recognized some of the ideas that Charles Darwin had been privately developing for some time; and in 1858, during a malarial attack on the island of Ternate in the South Moluccas, he conceived a fully rounded notion of evolution by what we now know as natural selection. He immediately wrote this up as a manuscript titled *On the Tendency of Varieties to Depart Indefinitely from the Original Type* and sent it to Darwin himself.

This of course created a quandary for Darwin, who wrote to a colleague that “If Wallace had had my manuscript sketch written out in 1844 he could not have made a better short abstract!” The problem of priority in the authorship of the concept of evolution by natural selection was rapidly resolved by the simultaneous presentation of Wallace’s manuscript and some extracts from Darwin’s published work to the Linnaean Society of London on July 1, 1858. Surprisingly in retrospect, this event seems to have passed largely unnoticed, and it was not until the next year, when Darwin’s hastily written work *On the Origin of Species* was published, that everyone sat up and took notice.

Following his return to England in 1862, Wallace wrote industriously, producing a stream of insightful books (one of them, with typically self-effacing modesty, entitled *Darwinism* [1899]). However, the rest of his career was lived very much in Darwin’s shadow, and despite being awarded various honors, Wallace never fully received the recognition due him. Indeed, for the entire remainder of his long life he was unable to secure a professional appointment.

A staunch advocate of natural selection in all other areas, Wallace nonetheless had difficulty discerning how this concept related to human evolution. In hindsight, Wallace’s perception in this matter may actually be seen as quite penetrating; but his choice of supernatural guidance as an alternative mechanism for the emergence of the unique human consciousness brought disapprobation in his own time and since. Although perhaps justifiable in this limited instance, such disapproval unfortunately continues, a century later, to cast a disproportionate shadow over this great scientist’s reputation.

— Ian Tattersall and Kenneth Mowbray

WALLACE, ANTHONY F. C. (1923–)

Anthony F. C. Wallace, born April 15, 1923, is a Canadian-born American anthropologist and historian best known for his work in community studies and ethnohistory, particularly social changes triggered by technological change. He received a PhD in 1950 from the University of Pennsylvania in Philadelphia where he taught from 1951 to 1988.

Wallace’s book *The Death and Rebirth of the Seneca* (1970) is a classic ethnohistorical study. The book highlights an Iroquois cultural revitalization in the 1800s following acute stress on Iroquois culture. The Iroquois were experiencing social and cultural collapse. The book focuses on Handsome Lake, the Seneca prophet who began preaching to the Iroquois after the Creator spoke to him following a miraculous recovery in the face of death. Handsome Lake had a series of visions in which the Creator gave instructions to the Iroquois to adapt their culture to farming and to practice the values of temperance, peace, land retention, and morality. Wallace traces Handsome Lake’s journey preaching to the Iroquois. The Code of Handsome Lake is still practiced today in Iroquois communities in Canada and the United States. Wallace was interested in how cultures adapted and changed in the wake of immense pressure caused by technological change.

His most important work is *Rockdale: The Growth of an American Village in the Early Industrial Revolution* (1978), for which he received the Bancroft Prize in 1979. The book links technological changes to the structure of community.

Wallace developed the concept of *mazeway* in reference to cognitive maps. The idea was elaborated in his writings on religion, social change, and revitalization. Wallace’s book *Religion: An Anthropological View* (1966) is a classic in the field. He writes that

religion is “a set of rituals, rationalized by myth, which mobilizes supernatural powers for the purpose of achieving or preventing transformation of state in man and nature.”

Ethnohistorians have shown how *now* is a social concept of time and the study of social life is a study of change over time. Here, Wallace offers insight to his view of history:

Everyone in every culture lives in some sort of historical time, though it might not be perceived in the same way an outside observer sees it. It's an interesting question, “When is Now?” “Now” can be drawn from some point like this hour, this day, this month, this lifetime, or this generation. “Now” can also have occurred centuries ago; things like unfair treaties, the Trail of Tears, and the Black Hawk War, for instance, remain part of the “Now” from which many Native Americans view their place in time today. Human beings respond today to people and events that actually occurred hundreds or even thousands of years ago.

WALLERSTEIN, IMMANUEL (1930–)

Immanuel Wallerstein was born in New York in 1930. He attended Columbia University where he received his BA in 1951, his MA in 1954, and his PhD in 1959. He then continued to lecture at Columbia until 1971. Wallerstein became a Professor of Sociology at McGill University in 1971 and in 1976 he joined the Department of Sociology at the State University of New York (SUNY) in Binghamton. During his career as a sociologist, historian, and philosopher, Wallerstein lectured across the nation and around the world. He was the head of the Fernand Braudel Center for the study of Economics, Historical

Systems, and Civilization. He also held the position of Directeur d'études associé at the Ecole des Hautes Etudes en Sciences Sociales in Paris. Wallerstein was president of the International Sociological Association from 1994–1998 and was the chair of the International Gulbenkian Commission on the Resurrecting of the Social Sciences from 1993–1995. He retired in 1999.

In 1974, Wallerstein published his political economy theory of modern world system. World-system theory asserts that worldwide division of labor is not formed by political or cultural boundaries, but by different social structures and member groups. These groups are self-contained within boundaries and held together by constant tension, which may at any time destroy the system. Wallerstein argues that there have only been two different types of world-systems: a world empire and capitalism. A world empire relies on political and military control. Capitalism relies on economic factors to maintain control. In capitalist society, the bourgeois capitalists from the core regions, primarily Europe and America, exploit the proletarians of the periphery, who provide the raw materials necessary for production. In this system there is also a semiperiphery, which contains areas that are exploiting others while at the same time being exploited themselves. Wallerstein claims that a third world-system, a socialist world government, may arise, in which division of labor would be determined by both political and economic factors.

Wallerstein's theory of world systems examines colonialism, postcolonialism, and political discourse. It contributes to the historical context of anthropological analysis in its examination of the alienation of labor. In his examination of the history of the development of global capitalism, Wallerstein acknowledges its negative effects on noncapitalist peoples. Global capitalism is sustained by unequal exchange. Wallerstein argues that the wealth of some nations cannot occur without the poverty of other nations. Due to Wallerstein's intellectual leadership, many more political economy theories emerged in the late 20th century, reflecting a broader intellectual disenchantment with the philosophical foundations of Western society. Immanuel Wallerstein contributed to the intensity with which anthropologists began to reflect on the role of sociocultural anthropology in academia and the world.

**WAR, ANTHROPOLOGY OF**

War is armed combat (fighting with weapons) between warriors or soldiers from two different political communities. This definition puts emphasis on learning to use weapons because learning to use weapons is socialization for armed combat. Warfare by definition is differentiated from other forms of killing—those that occur within political communities; these are, namely, homicide, political assassination (unless it is the leader of another polity), feuding, capital punishment, dueling, and human sacrifice. The study of war should focus upon pairs of political communities or pairs of alliances (of course, a single political community could be at war with an alliance). The warfare that occurs over a period of time between two rival entities (political communities or alliances) constitutes a “warfare system.” An intergroup relations approach is useful in analyzing warfare systems: how relationships between polities influence relationships within polities and how these in turn influence relationships between polities. Each warfare system is unique.

Examination of the best-known warring societies makes it clear that warfare systems are so different that their comparison as wholes is difficult. Famous warring societies in the ethnographic record include the Alaskan Eskimo, Andamanese, Balona, Cherokee, Cheyenne and Sioux, Dani, Figi, Higi, Iban, Ifugao and Kalinga, Iroquois and Huron, Jivaro, Kofyar, Kwakiutl, Māori, Maring, Mohave, Montenegro, Mundurucu, Murngin, Navaho, Nuer and Dinka, Pima and Papago, Tausug, Tibetans, Tiwi, Tonga, Waorani, Western Apache, Yanamamo, Yoroba, and Zulu. Archaeologically known warring societies include the Aztec, Easter Islanders, Greek Hoplites, Inca, Maya (once considered peaceful), Moche, Samurai Japan, Shang

Chinese, Sumerians, and Zapotec. For comprehensive bibliographies see Divale (1973) and Ferguson (1988).

Anthropologists who study war have found that war is a near universal; it occurs with great frequency at all levels of sociopolitical complexity. Societies without war are rare. Even societies without war may be part of a *warfare system*. For example, a hunting-gathering people such as the peaceful Semai of Southeast Asia have been attacked so frequently that they have become a refugee group or enclaved people. The two most common reasons why a few societies are peaceful are that, at the time they were studied, they had been conquered and become a dependent native people or they had long lived in an isolated area or been recently driven to one. Otterbein found four such societies in his cross-cultural study of war: Copper Eskimo, Dorobo, Tikopia, and Toda.
